MANUAL

1	Introduction	3
1.1	History of Yosys	3
1.2	Structure of this document	4
2	Basic principles	5
2.1	Levels of abstraction	5
2.2	Features of synthesizable Verilog	8
2.3	Challenges in digital circuit synthesis	12
2.4	Script-based synthesis flows	13
2.5	Methods from compiler design	14
3	Approach	19
3.1	Data- and control-flow	19
3.2	Internal formats in Yosys	20
3.3	Typical use case	20
4	Implementation overview	23
4.1	Simplified data flow	23
4.2	The RTL Intermediate Language (RTLIL)	24
4.3	Command interface and synthesis scripts	31
4.4	Source tree and build system	31
5	Internal cell library	33
5.1	RTL cells	33
5.2	Gates	42
6	Programming Yosys extensions	49
6.1	Guidelines	49
6.2	The “stubsnets” example module	55
7	The Verilog and AST frontends	59
7.1	Transforming Verilog to AST	60
7.2	Transforming AST to RTLIL	62
7.3	Synthesizing Verilog always blocks	63
7.4	Synthesizing Verilog arrays	68
7.5	Synthesizing parametric designs	69
8	Optimizations	71
8.1	Simple optimizations	71
8.2	FSM extraction and encoding	73
8.3	Logic optimization	76

9	Technology mapping	77
9.1	Cell substitution	77
9.2	Subcircuit substitution	77
9.3	Gate-level technology mapping	78
10	Memory mapping	79
10.1	Additional notes	79
10.2	Simple dual port (SDP) memory patterns	81
10.3	Single-port RAM memory patterns	84
10.4	Read register reset patterns	86
10.5	Asymmetric memory patterns	87
10.6	True dual port (TDP) patterns	89
10.7	Not yet supported patterns	90
10.8	Undesired patterns	91
A	Auxiliary libraries	93
A.1	SHA1	93
A.2	BigInt	93
A.3	SubCircuit	93
A.4	ezSAT	93
B	Auxiliary programs	95
B.1	yosys-config	95
B.2	yosys-filterlib	95
B.3	yosys-abc	95
C	RTLIL text representation	97
C.1	Lexical elements	97
C.2	File	98
D	010: Converting Verilog to BLIF page	103
D.1	Installation	103
D.2	Getting started	103
D.3	Using a synthesis script	104
D.4	Advanced example: The Amber23 ARMv2a CPU	105
D.5	Verification of the Amber23 CPU	107
D.6	Limitations	107
D.7	Conclusion	108
E	011: Interactive design investigation page	109
E.1	Installation and prerequisites	109
E.2	Overview	109
E.3	Introduction to the show command	109
E.4	Navigating the design	115
E.5	Advanced investigation techniques	123
E.6	Conclusion	130
F	012: Converting Verilog to BTOR page	131
F.1	Installation	131
F.2	Quick start	131
F.3	Detailed flow	133
F.4	Example	134
F.5	Limitations	136
F.6	Conclusion	136

G	Command line reference	137
G.1	abc - use ABC for technology mapping	137
G.2	abc9 - use ABC9 for technology mapping	141
G.3	abc9_exe - use ABC9 for technology mapping	144
G.4	abc9_ops - helper functions for ABC9	145
G.5	add - add objects to the design	147
G.6	aigmap - map logic to and-inverter-graph circuit	147
G.7	alumacc - extract ALU and MACC cells	148
G.8	anlogic_eqn - Anlogic: Calculate equations for luts	148
G.9	anlogic_fixcarry - Anlogic: fix carry chain	148
G.10	assertpmux - adds asserts for parallel muxes	148
G.11	async2sync - convert async FF inputs to sync circuits	148
G.12	attrmap - renaming attributes	149
G.13	attrmvcp - move or copy attributes from wires to driving cells	149
G.14	autoname - automatically assign names to objects	150
G.15	blackbox - convert modules into blackbox modules	150
G.16	bmuxmap - transform \$bmux cells to trees of \$mux cells	150
G.17	bugpoint - minimize testcases	151
G.18	bwmuxmap - replace \$bwmux cells with equivalent logic	152
G.19	cd - a shortcut for 'select -module <name>'	152
G.20	check - check for obvious problems in the design	153
G.21	chformal - change formal constraints of the design	153
G.22	chparam - re-evaluate modules with new parameters	154
G.23	chtype - change type of cells in the design	154
G.24	clean - remove unused cells and wires	155
G.25	clean_zerowidth - clean zero-width connections from the design	155
G.26	clk2fflogic - convert clocked FFs to generic \$ff cells	155
G.27	clkbufmap - insert clock buffers on clock networks	155
G.28	connect - create or remove connections	156
G.29	connect_rpc - connect to RPC frontend	157
G.30	connwrappers - match width of input-output port pairs	157
G.31	coolrunner2_fixup - insert necessary buffer cells for CoolRunner-II architecture	158
G.32	coolrunner2_sop - break \$sop cells into ANDTERM/ORTERM cells	158
G.33	copy - copy modules in the design	158
G.34	cover - print code coverage counters	158
G.35	cutpoint - adds formal cut points to the design	159
G.36	debug - run command with debug log messages enabled	160
G.37	delete - delete objects in the design	160
G.38	deminout - demote inout ports to input or output	160
G.39	demuxmap - transform \$demux cells to \$eq + \$mux cells	160
G.40	design - save, restore and reset current design	160
G.41	dffinit - set INIT param on FF cells	162
G.42	dfflegalize - convert FFs to types supported by the target	162
G.43	dfflibmap - technology mapping of flip-flops	164
G.44	dffunmap - unmap clock enable and synchronous reset from FFs	164
G.45	dump - print parts of the design in RTLIL format	164
G.46	echo - turning echoing back of commands on and off	165
G.47	ecp5_gsr - ECP5: handle GSR	165
G.48	edgetypes - list all types of edges in selection	165
G.49	efinix_fixcarry - Efinix: fix carry chain	166
G.50	equiv_add - add a \$equiv cell	166
G.51	equiv_induct - proving \$equiv cells using temporal induction	166
G.52	equiv_make - prepare a circuit for equivalence checking	167
G.53	equiv_mark - mark equivalence checking regions	167

G.54	equiv_miter - extract miter from equiv circuit	167
G.55	equiv_opt - prove equivalence for optimized circuit	168
G.56	equiv_purge - purge equivalence checking module	169
G.57	equiv_remove - remove \$equiv cells	169
G.58	equiv_simple - try proving simple \$equiv instances	170
G.59	equiv_status - print status of equivalent checking module	170
G.60	equiv_struct - structural equivalence checking	170
G.61	eval - evaluate the circuit given an input	171
G.62	exec - execute commands in the operating system shell	171
G.63	expose - convert internal signals to module ports	172
G.64	extract - find subcircuits and replace them with cells	173
G.65	extract_counter - Extract GreenPak4 counter cells	174
G.66	extract_fa - find and extract full/half adders	175
G.67	extract_reduce - converts gate chains into \$reduce_* cells	175
G.68	extractinv - extract explicit inverter cells for invertible cell pins	176
G.69	flatten - flatten design	176
G.70	flowmap - pack LUTs with FlowMap	176
G.71	fmcombine - combine two instances of a cell into one	177
G.72	fmnit - set init values/sequences for formal	178
G.73	formalff - prepare FFs for formal	178
G.74	freduce - perform functional reduction	179
G.75	fsm - extract and optimize finite state machines	180
G.76	fsm_detect - finding FSMs in design	181
G.77	fsm_expand - expand FSM cells by merging logic into it	181
G.78	fsm_export - exporting FSMs to KISS2 files	181
G.79	fsm_extract - extracting FSMs in design	182
G.80	fsm_info - print information on finite state machines	182
G.81	fsm_map - mapping FSMs to basic logic	182
G.82	fsm_opt - optimize finite state machines	182
G.83	fsm_recode - recoding finite state machines	183
G.84	fst2tb - generate testbench out of fst file	183
G.85	gatamate_foldinv - fold inverters into Gatamate LUT trees	184
G.86	glift - create GLIFT models and optimization problems	184
G.87	greenpak4_dffinv - merge greenpak4 inverters and DFF/latches	186
G.88	help - display help messages	186
G.89	hierarchy - check, expand and clean up design hierarchy	186
G.90	hilomap - technology mapping of constant hi- and/or lo-drivers	188
G.91	history - show last interactive commands	188
G.92	ice40_braminit - iCE40: perform SB_RAM40_4K initialization from file	188
G.93	ice40_dsp - iCE40: map multipliers	188
G.94	ice40_opt - iCE40: perform simple optimizations	189
G.95	ice40_wrapcarry - iCE40: wrap carries	189
G.96	insbuf - insert buffer cells for connected wires	189
G.97	iopadmap - technology mapping of i/o pads (or buffers)	190
G.98	jny - write design and metadata	191
G.99	json - write design in JSON format	191
G.100	log - print text and log files	192
G.101	logger - set logger properties	192
G.102	ls - list modules or objects in modules	193
G.103	ltp - print longest topological path	193
G.104	lut2mux - convert \$lut to \$__MUX__	193
G.105	maccmap - mapping macc cells	194
G.106	memory - translate memories to basic cells	194
G.107	memory_bmux2rom - convert muxes to ROMs	194

G.108	memory_bram - map memories to block rams	194
G.109	memory_collect - creating multi-port memory cells	197
G.110	memory_dff - merge input/output DFFs into memory read ports	197
G.111	memory_libmap - map memories to cells	197
G.112	memory_map - translate multiport memories to basic cells	198
G.113	memory_memx - emulate vlog sim behavior for mem ports	198
G.114	memory_narrow - split up wide memory ports	198
G.115	memory_nordff - extract read port FFs from memories	199
G.116	memory_share - consolidate memory ports	199
G.117	memory_unpack - unpack multi-port memory cells	199
G.118	miter - automatically create a miter circuit	199
G.119	mutate - generate or apply design mutations	201
G.120	muxcover - cover trees of MUX cells with wider MUXes	202
G.121	muxpack - \$mux/\$pmux cascades to \$pmux	202
G.122	nlutmap - map to LUTs of different sizes	203
G.123	onehot - optimize \$eq cells for onehot signals	203
G.124	opt - perform simple optimizations	203
G.125	opt_clean - remove unused cells and wires	204
G.126	opt_demorgan - Optimize reductions with DeMorgan equivalents	204
G.127	opt_dff - perform DFF optimizations	205
G.128	opt_expr - perform const folding and simple expression rewriting	205
G.129	opt_ffinv - push inverters through FFs	206
G.130	opt_lut - optimize LUT cells	206
G.131	opt_lut_ins - discard unused LUT inputs	206
G.132	opt_mem - optimize memories	207
G.133	opt_mem_feedback - convert memory read-to-write port feedback paths to write enables	207
G.134	opt_mem_priority - remove priority relations between write ports that can never collide	207
G.135	opt_mem_widen - optimize memories where all ports are wide	207
G.136	opt_merge - consolidate identical cells	208
G.137	opt_muxtree - eliminate dead trees in multiplexer trees	208
G.138	opt_reduce - simplify large MUXes and AND/OR gates	208
G.139	opt_share - merge mutually exclusive cells of the same type that share an input signal	209
G.140	paramap - renaming cell parameters	209
G.141	peepopt - collection of peephole optimizers	210
G.142	plugin - load and list loaded plugins	210
G.143	pmux2shiftx - transform \$pmux cells to \$shiftx cells	210
G.144	pmuxtree - transform \$pmux cells to trees of \$mux cells	211
G.145	portlist - list (top-level) ports	211
G.146	prep - generic synthesis script	211
G.147	printattrs - print attributes of selected objects	212
G.148	proc - translate processes to netlists	213
G.149	proc_arst - detect asynchronous resets	213
G.150	proc_clean - remove empty parts of processes	214
G.151	proc_dff - extract flip-flops from processes	214
G.152	proc_dlatch - extract latches from processes	214
G.153	proc_init - convert initial block to init attributes	214
G.154	proc_memwr - extract memory writes from processes	215
G.155	proc_mux - convert decision trees to multiplexers	215
G.156	proc_prune - remove redundant assignments	215
G.157	proc_rmdead - eliminate dead trees in decision trees	215
G.158	proc_rom - convert switches to ROMs	215
G.159	qbfsat - solve a 2QBF-SAT problem in the circuit	216
G.160	qwp - quadratic wirelength placer	217
G.161	read - load HDL designs	218

G.162read_aiger - read AIGER file	219
G.163read_blif - read BLIF file	219
G.164read_ilang - (deprecated) alias of read_rtlil	220
G.165read_json - read JSON file	220
G.166read_liberty - read cells from liberty file	220
G.167read_rtlil - read modules from RTLIL file	221
G.168read_verilog - read modules from Verilog file	221
G.169recover_names - Execute a lossy mapping command and recover original netnames	224
G.170rename - rename object in the design	224
G.171rmports - remove module ports with no connections	226
G.172sat - solve a SAT problem in the circuit	226
G.173scatter - add additional intermediate nets	229
G.174scc - detect strongly connected components (logic loops)	229
G.175scratchpad - get/set values in the scratchpad	230
G.176script - execute commands from file or wire	231
G.177select - modify and view the list of selected objects	231
G.178setattr - set/unset attributes on objects	236
G.179setparam - set/unset parameters on objects	236
G.180setundef - replace undef values with defined constants	236
G.181share - perform sat-based resource sharing	237
G.182shell - enter interactive command mode	237
G.183show - generate schematics using graphviz	238
G.184shregmap - map shift registers	240
G.185sim - simulate the circuit	241
G.186simplemap - mapping simple coarse-grain cells	243
G.187splice - create explicit splicing cells	243
G.188splitcells - split up multi-bit cells	244
G.189splitnets - split up multi-bit nets	244
G.190sta - perform static timing analysis	245
G.191stat - print some statistics	245
G.192submod - moving part of a module to a new submodule	246
G.193supercover - add hi/lo cover cells for each wire bit	246
G.194synth - generic synthesis script	246
G.195synth_achronix - synthesis for Achronix Speedster22i FPGAs.	248
G.196synth_anlogic - synthesis for Anlogic FPGAs	250
G.197synth_coolrunner2 - synthesis for Xilinx Coolrunner-II CPLDs	252
G.198synth_easic - synthesis for eASIC platform	253
G.199synth_ecp5 - synthesis for ECP5 FPGAs	255
G.200synth_efinix - synthesis for Efinix FPGAs	258
G.201synth_fabulous - FABulous synthesis script	260
G.202synth_gatamate - synthesis for Cologne Chip GateMate FPGAs	263
G.203synth_gowin - synthesis for Gowin FPGAs	266
G.204synth_greenpak4 - synthesis for GreenPAK4 FPGAs	268
G.205synth_ice40 - synthesis for iCE40 FPGAs	270
G.206synth_intel - synthesis for Intel (Altera) FPGAs.	274
G.207synth_intel_alm - synthesis for ALM-based Intel (Altera) FPGAs.	276
G.208synth_machxo2 - synthesis for MachXO2 FPGAs. This work is experimental.	278
G.209synth_nexus - synthesis for Lattice Nexus FPGAs	281
G.210synth_quicklogic - Synthesis for QuickLogic FPGAs	284
G.211synth_sf2 - synthesis for SmartFusion2 and IGLOO2 FPGAs	286
G.212synth_xilinx - synthesis for Xilinx FPGAs	288
G.213synthprop - synthesize SVA properties	292
G.214tcl - execute a TCL script file	292
G.215techmap - generic technology mapper	293

G.216tee - redirect command output to file	296
G.217test_abcloop - automatically test handling of loops in abc command	296
G.218test_autotb - generate simple test benches	297
G.219test_cell - automatically test the implementation of a cell type	297
G.220test_pmgen - test pass for pmgen	298
G.221torder - print cells in topological order	299
G.222trace - redirect command output to file	299
G.223tribuf - infer tri-state buffers	299
G.224uniquify - create unique copies of modules	300
G.225verific - load Verilog and VHDL designs using Verific	300
G.226verilog_defaults - set default options for read_verilog	304
G.227verilog_defines - define and undefine verilog defines	304
G.228viz - visualize data flow graph	305
G.229wbflip - flip the whitebox attribute	306
G.230wreduce - reduce the word size of operations if possible	306
G.231write_aiger - write design to AIGER file	307
G.232write_blif - write design to BLIF file	307
G.233write_btor - write design to BTOR file	309
G.234write_cxxrtl - convert design to C++ RTL simulation	309
G.235write_edif - write design to EDIF netlist file	314
G.236write_file - write a text to a file	315
G.237write_firrtl - write design to a FIRRTL file	315
G.238write_ilang - (deprecated) alias of write_rtlil	315
G.239write_intersynth - write design to InterSynth netlist file	315
G.240write_jny - generate design metadata	316
G.241write_json - write design to a JSON file	316
G.242write_rtlil - write design to RTLIL file	321
G.243write_simplec - convert design to simple C code	321
G.244write_smt2 - write design to SMT-LIBv2 file	322
G.245write_smv - write design to SMV file	325
G.246write_spice - write design to SPICE netlist file	325
G.247write_table - write design as connectivity table	326
G.248write_verilog - write design to Verilog file	326
G.249write_xaiger - write design to XAIGER file	328
G.250xilinx_dffopt - Xilinx: optimize FF control signal usage	328
G.251xilinx_dsp - Xilinx: pack resources into DSPs	328
G.252xilinx_srl - Xilinx shift register extraction	329
G.253xprop - formal x propagation	330
G.254zinit - add inverters so all FF are zero-initialized	331

Abstract

Most of today's digital design is done in HDL code (mostly Verilog or VHDL) and with the help of HDL synthesis tools.

In special cases such as synthesis for coarse-grain cell libraries or when testing new synthesis algorithms it might be necessary to write a custom HDL synthesis tool or add new features to an existing one. In these cases the availability of a Free and Open Source (FOSS) synthesis tool that can be used as basis for custom tools would be helpful.

In the absence of such a tool, the Yosys Open SYnthesis Suite (Yosys) was developed. This document covers the design and implementation of this tool. At the moment the main focus of Yosys lies on the high-level aspects of digital synthesis. The pre-existing FOSS logic-synthesis tool ABC is used by Yosys to perform advanced gate-level optimizations.

An evaluation of Yosys based on real-world designs is included. It is shown that Yosys can be used as-is to synthesize such designs. The results produced by Yosys in this tests were successfully verified using formal verification and are comparable in quality to the results produced by a commercial synthesis tool.

This document was originally published as bachelor thesis at the Vienna University of Technology [Wol13].

INTRODUCTION

This document presents the Free and Open Source (FOSS) Verilog HDL synthesis tool “Yosys”. Its design and implementation as well as its performance on real-world designs is discussed in this document.

1.1 History of Yosys

A Hardware Description Language (HDL) is a computer language used to describe circuits. A HDL synthesis tool is a computer program that takes a formal description of a circuit written in an HDL as input and generates a netlist that implements the given circuit as output.

Currently the most widely used and supported HDLs for digital circuits are Verilog [A+02, A+06] and VHDL (VHSIC HDL, where VHSIC is an acronym for Very-High-Speed Integrated Circuits) [A+04, A+09]. Both HDLs are used for test and verification purposes as well as logic synthesis, resulting in a set of synthesizable and a set of non-synthesizable language features. In this document we only look at the synthesizable subset of the language features.

In recent work on heterogeneous coarse-grain reconfigurable logic [WGS+12] the need for a custom application-specific HDL synthesis tool emerged. It was soon realised that a synthesis tool that understood Verilog or VHDL would be preferred over a synthesis tool for a custom HDL. Given an existing Verilog or VHDL front end, the work for writing the necessary additional features and integrating them in an existing tool can be estimated to be about the same as writing a new tool with support for a minimalistic custom HDL.

The proposed custom HDL synthesis tool should be licensed under a Free and Open Source Software (FOSS) licence. So an existing FOSS Verilog or VHDL synthesis tool would have been needed as basis to build upon. The main advantages of choosing Verilog or VHDL is the ability to synthesize existing HDL code and to mitigate the requirement for circuit-designers to learn a new language. In order to take full advantage of any existing FOSS Verilog or VHDL tool, such a tool would have to provide a feature-complete implementation of the synthesizable HDL subset.

Basic RTL synthesis is a well understood field [HS96]. Lexing, parsing and processing of computer languages [ASU86] is a thoroughly researched field. All the information required to write such tools has been openly available for a long time, and it is therefore likely that a FOSS HDL synthesis tool with a feature-complete Verilog or VHDL front end must exist which can be used as a basis for a custom RTL synthesis tool.

Due to the author’s preference for Verilog over VHDL it was decided early on to go for Verilog instead of VHDL¹. So the existing FOSS Verilog synthesis tools were evaluated. The results of this evaluation are utterly devastating. Therefore a completely new Verilog synthesis tool was implemented and is recommended as basis for custom synthesis tools. This is the tool that is discussed in this document.

¹ A quick investigation into FOSS VHDL tools yielded similar grim results for FOSS VHDL synthesis tools.

1.2 Structure of this document

The structure of this document is as follows:

[Chapter 1](#) is this introduction.

[Chapter 2](#) covers a short introduction to the world of HDL synthesis. Basic principles and the terminology are outlined in this chapter.

[Chapter 3](#) gives the quickest possible outline to how the problem of implementing a HDL synthesis tool is approached in the case of Yosys.

[Chapter 4](#) contains a more detailed overview of the implementation of Yosys. This chapter covers the data structures used in Yosys to represent a design in detail and is therefore recommended reading for everyone who is interested in understanding the Yosys internals.

[Chapter 5](#) covers the internal cell library used by Yosys. This is especially important knowledge for anyone who wants to understand the intermediate netlists used internally by Yosys.

[Chapter 6](#) gives a tour to the internal APIs of Yosys. This is recommended reading for everyone who actually wants to read or write Yosys source code. The chapter concludes with an example loadable module for Yosys.

Chapters [7](#), [8](#) and [9](#) cover three important pieces of the synthesis pipeline: The Verilog frontend, the optimization passes and the technology mapping to the target architecture, respectively.

Various appendices, including a *Command line reference*, complete this document.

BASIC PRINCIPLES

This chapter contains a short introduction to the basic principles of digital circuit synthesis.

2.1 Levels of abstraction

Digital circuits can be represented at different levels of abstraction. During the design process a circuit is usually first specified using a higher level abstraction. Implementation can then be understood as finding a functionally equivalent representation at a lower abstraction level. When this is done automatically using software, the term synthesis is used.

So synthesis is the automatic conversion of a high-level representation of a circuit to a functionally equivalent low-level representation of a circuit. [Figure 2.1](#) lists the different levels of abstraction and how they relate to different kinds of synthesis.

Fig. 2.1: Different levels of abstraction and synthesis.

Regardless of the way a lower level representation of a circuit is obtained (synthesis or manual design), the lower level representation is usually verified by comparing simulation results of the lower level and the higher level representation¹. Therefore even if no synthesis is used, there must still be a simulatable representation of the circuit in all levels to allow for verification of the design.

¹ In recent years formal equivalence checking also became an important verification method for validating RTL and lower abstraction representation of the design.

Note: The exact meaning of terminology such as “High-Level” is of course not fixed over time. For example the HDL “ABEL” was first introduced in 1985 as “A High-Level Design Language for Programmable Logic Devices” [LHBB85], but would not be considered a “High-Level Language” today.

2.1.1 System level

The System Level abstraction of a system only looks at its biggest building blocks like CPUs and computing cores. At this level the circuit is usually described using traditional programming languages like C/C++ or Matlab. Sometimes special software libraries are used that are aimed at simulation circuits on the system level, such as SystemC.

Usually no synthesis tools are used to automatically transform a system level representation of a circuit to a lower-level representation. But system level design tools exist that can be used to connect system level building blocks.

The IEEE 1685-2009 standard defines the IP-XACT file format that can be used to represent designs on the system level and building blocks that can be used in such system level designs. [A+10]

2.1.2 High level

The high-level abstraction of a system (sometimes referred to as algorithmic level) is also often represented using traditional programming languages, but with a reduced feature set. For example when representing a design at the high level abstraction in C, pointers can only be used to mimic concepts that can be found in hardware, such as memory interfaces. Full featured dynamic memory management is not allowed as it has no corresponding concept in digital circuits.

Tools exist to synthesize high level code (usually in the form of C/C++/SystemC code with additional metadata) to behavioural HDL code (usually in the form of Verilog or VHDL code). Aside from the many commercial tools for high level synthesis there are also a number of FOSS tools for high level synthesis .

2.1.3 Behavioural level

At the behavioural abstraction level a language aimed at hardware description such as Verilog or VHDL is used to describe the circuit, but so-called behavioural modelling is used in at least part of the circuit description. In behavioural modelling there must be a language feature that allows for imperative programming to be used to describe data paths and registers. This is the `always`-block in Verilog and the `process`-block in VHDL.

In behavioural modelling, code fragments are provided together with a sensitivity list; a list of signals and conditions. In simulation, the code fragment is executed whenever a signal in the sensitivity list changes its value or a condition in the sensitivity list is triggered. A synthesis tool must be able to transfer this representation into an appropriate datapath followed by the appropriate types of register.

For example consider the following Verilog code fragment:

```
1 always @(posedge clk)
2     y <= a + b;
```

In simulation the statement `y <= a + b` is executed whenever a positive edge on the signal `clk` is detected. The synthesis result however will contain an adder that calculates the sum `a + b` all the time, followed by a d-type flip-flop with the adder output on its D-input and the signal `y` on its Q-output.

Usually the imperative code fragments used in behavioural modelling can contain statements for conditional execution (`if`- and `case`-statements in Verilog) as well as loops, as long as those loops can be completely unrolled.

Interestingly there seems to be no other FOSS Tool that is capable of performing Verilog or VHDL behavioural syntheses besides Yosys.

2.1.4 Register-Transfer Level (RTL)

On the Register-Transfer Level the design is represented by combinatorial data paths and registers (usually d-type flip flops). The following Verilog code fragment is equivalent to the previous Verilog example, but is in RTL representation:

```

1 assign tmp = a + b;          // combinatorial data path
2
3 always @(posedge clk)       // register
4     y <= tmp;
```

A design in RTL representation is usually stored using HDLs like Verilog and VHDL. But only a very limited subset of features is used, namely minimalistic always-blocks (Verilog) or process-blocks (VHDL) that model the register type used and unconditional assignments for the datapath logic. The use of HDLs on this level simplifies simulation as no additional tools are required to simulate a design in RTL representation.

Many optimizations and analyses can be performed best at the RTL level. Examples include FSM detection and optimization, identification of memories or other larger building blocks and identification of shareable resources.

Note that RTL is the first abstraction level in which the circuit is represented as a graph of circuit elements (registers and combinatorial cells) and signals. Such a graph, when encoded as list of cells and connections, is called a netlist.

RTL synthesis is easy as each circuit node element in the netlist can simply be replaced with an equivalent gate-level circuit. However, usually the term RTL synthesis does not only refer to synthesizing an RTL netlist to a gate level netlist but also to performing a number of highly sophisticated optimizations within the RTL representation, such as the examples listed above.

A number of FOSS tools exist that can perform isolated tasks within the domain of RTL synthesis steps. But there seems to be no FOSS tool that covers a wide range of RTL synthesis operations.

2.1.5 Logical gate level

At the logical gate level the design is represented by a netlist that uses only cells from a small number of single-bit cells, such as basic logic gates (AND, OR, NOT, XOR, etc.) and registers (usually D-Type Flip-flops).

A number of netlist formats exists that can be used on this level, e.g. the Electronic Design Interchange Format (EDIF), but for ease of simulation often a HDL netlist is used. The latter is a HDL file (Verilog or VHDL) that only uses the most basic language constructs for instantiation and connecting of cells.

There are two challenges in logic synthesis: First finding opportunities for optimizations within the gate level netlist and second the optimal (or at least good) mapping of the logic gate netlist to an equivalent netlist of physically available gate types.

The simplest approach to logic synthesis is two-level logic synthesis, where a logic function is converted into a sum-of-products representation, e.g. using a Karnaugh map. This is a simple approach, but has exponential worst-case effort and cannot make efficient use of physical gates other than AND/NAND-, OR/NOR- and NOT-Gates.

Therefore modern logic synthesis tools utilize much more complicated multi-level logic synthesis algorithms [BHSV90]. Most of these algorithms convert the logic function to a Binary-Decision-Diagram (BDD) or

And-Inverter-Graph (AIG) and work from that representation. The former has the advantage that it has a unique normalized form. The latter has much better worst case performance and is therefore better suited for the synthesis of large logic functions.

Good FOSS tools exist for multi-level logic synthesis .

Yosys contains basic logic synthesis functionality but can also use ABC for the logic synthesis step. Using ABC is recommended.

2.1.6 Physical gate level

On the physical gate level only gates are used that are physically available on the target architecture. In some cases this may only be NAND, NOR and NOT gates as well as D-Type registers. In other cases this might include cells that are more complex than the cells used at the logical gate level (e.g. complete half-adders). In the case of an FPGA-based design the physical gate level representation is a netlist of LUTs with optional output registers, as these are the basic building blocks of FPGA logic cells.

For the synthesis tool chain this abstraction is usually the lowest level. In case of an ASIC-based design the cell library might contain further information on how the physical cells map to individual switches (transistors).

2.1.7 Switch level

A switch level representation of a circuit is a netlist utilizing single transistors as cells. Switch level modelling is possible in Verilog and VHDL, but is seldom used in modern designs, as in modern digital ASIC or FPGA flows the physical gates are considered the atomic build blocks of the logic circuit.

2.1.8 Yosys

Yosys is a Verilog HDL synthesis tool. This means that it takes a behavioural design description as input and generates an RTL, logical gate or physical gate level description of the design as output. Yosys' main strengths are behavioural and RTL synthesis. A wide range of commands (synthesis passes) exist within Yosys that can be used to perform a wide range of synthesis tasks within the domain of behavioural, rtl and logic synthesis. Yosys is designed to be extensible and therefore is a good basis for implementing custom synthesis tools for specialised tasks.

2.2 Features of synthesizable Verilog

The subset of Verilog [A+06] that is synthesizable is specified in a separate IEEE standards document, the IEEE standard 1364.1-2002 [A+02]. This standard also describes how certain language constructs are to be interpreted in the scope of synthesis.

This section provides a quick overview of the most important features of synthesizable Verilog, structured in order of increasing complexity.

2.2.1 Structural Verilog

Structural Verilog (also known as Verilog Netlists) is a Netlist in Verilog syntax. Only the following language constructs are used in this case:

- Constant values
- Wire and port declarations
- Static assignments of signals to other signals
- Cell instantiations

Many tools (especially at the back end of the synthesis chain) only support structural Verilog as input. ABC is an example of such a tool. Unfortunately there is no standard specifying what Structural Verilog actually is, leading to some confusion about what syntax constructs are supported in structural Verilog when it comes to features such as attributes or multi-bit signals.

2.2.2 Expressions in Verilog

In all situations where Verilog accepts a constant value or signal name, expressions using arithmetic operations such as `+`, `-` and `*`, boolean operations such as `&` (AND), `|` (OR) and `^` (XOR) and many others (comparison operations, unary operator, etc.) can also be used.

During synthesis these operators are replaced by cells that implement the respective function.

Many FOSS tools that claim to be able to process Verilog in fact only support basic structural Verilog and simple expressions. Yosys can be used to convert full featured synthesizable Verilog to this simpler subset, thus enabling such applications to be used with a richer set of Verilog features.

2.2.3 Behavioural modelling

Code that utilizes the Verilog `always` statement is using Behavioural Modelling. In behavioural modelling, a circuit is described by means of imperative program code that is executed on certain events, namely any change, a rising edge, or a falling edge of a signal. This is a very flexible construct during simulation but is only synthesizable when one of the following is modelled:

- **Asynchronous or latched logic**

In this case the sensitivity list must contain all expressions that are used within the `always` block.

The syntax `@*` can be used for these cases. Examples of this kind include:

```

1 // asynchronous
2 always @* begin
3     if (add_mode)
4         y <= a + b;
5     else
6         y <= a - b;
7 end
8
9 // latched
10 always @* begin
11     if (!hold)
12         y <= a + b;
13 end

```

Note that latched logic is often considered bad style and in many cases just the result of sloppy HDL design. Therefore many synthesis tools generate warnings whenever latched logic is generated.

- **Synchronous logic (with optional synchronous reset)**

This is logic with d-type flip-flops on the output. In this case the sensitivity list must only contain the respective clock edge. Example:

```
1 // counter with synchronous reset
2 always @(posedge clk) begin
3     if (reset)
4         y <= 0;
5     else
6         y <= y + 1;
7 end
```

- **Synchronous logic with asynchronous reset**

This is logic with d-type flip-flops with asynchronous resets on the output. In this case the sensitivity list must only contain the respective clock and reset edges. The values assigned in the reset branch must be constant. Example:

```
1 // counter with asynchronous reset
2 always @(posedge clk, posedge reset) begin
3     if (reset)
4         y <= 0;
5     else
6         y <= y + 1;
7 end
```

Many synthesis tools support a wider subset of flip-flops that can be modelled using always-statements (including Yosys). But only the ones listed above are covered by the Verilog synthesis standard and when writing new designs one should limit herself or himself to these cases.

In behavioural modelling, blocking assignments (=) and non-blocking assignments (<=) can be used. The concept of blocking vs. non-blocking assignment is one of the most misunderstood constructs in Verilog [CI00].

The blocking assignment behaves exactly like an assignment in any imperative programming language, while with the non-blocking assignment the right hand side of the assignment is evaluated immediately but the actual update of the left hand side register is delayed until the end of the time-step. For example the Verilog code `a <= b; b <= a;` exchanges the values of the two registers.

2.2.4 Functions and tasks

Verilog supports Functions and Tasks to bundle statements that are used in multiple places (similar to Procedures in imperative programming). Both constructs can be implemented easily by substituting the function/task-call with the body of the function or task.

2.2.5 Conditionals, loops and generate-statements

Verilog supports **if-else**-statements and **for**-loops inside **always**-statements.

It also supports both features in **generate**-statements on the module level. This can be used to selectively enable or disable parts of the module based on the module parameters (**if-else**) or to generate a set of similar subcircuits (**for**).

While the **if-else**-statement inside an **always**-block is part of behavioural modelling, the three other cases are (at least for a synthesis tool) part of a built-in macro processor. Therefore it must be possible for the synthesis tool to completely unroll all loops and evaluate the condition in all **if-else**-statement in **generate**-statements using const-folding..

2.2.6 Arrays and memories

Verilog supports arrays. This is in general a synthesizable language feature. In most cases arrays can be synthesized by generating addressable memories. However, when complex or asynchronous access patterns are used, it is not possible to model an array as memory. In these cases the array must be modelled using individual signals for each word and all accesses to the array must be implemented using large multiplexers.

In some cases it would be possible to model an array using memories, but it is not desired. Consider the following delay circuit:

```

1  module (clk, in_data, out_data);
2
3  parameter BITS = 8;
4  parameter STAGES = 4;
5
6  input clk;
7  input [BITS-1:0] in_data;
8  output [BITS-1:0] out_data;
9  reg [BITS-1:0] ffs [STAGES-1:0];
10
11 integer i;
12 always @(posedge clk) begin
13     ffs[0] <= in_data;
14     for (i = 1; i < STAGES; i = i+1)
15         ffs[i] <= ffs[i-1];
16 end
17
18 assign out_data = ffs[STAGES-1];
19
20 endmodule

```

This could be implemented using an addressable memory with STAGES input and output ports. A better implementation would be to use a simple chain of flip-flops (a so-called shift register). This better implementation can either be obtained by first creating a memory-based implementation and then optimizing it

based on the static address signals for all ports or directly identifying such situations in the language front end and converting all memory accesses to direct accesses to the correct signals.

2.3 Challenges in digital circuit synthesis

This section summarizes the most important challenges in digital circuit synthesis. Tools can be characterized by how well they address these topics.

2.3.1 Standards compliance

The most important challenge is compliance with the HDL standards in question (in case of Verilog the IEEE Standards 1364.1-2002 and 1364-2005). This can be broken down in two items:

- Completeness of implementation of the standard
- Correctness of implementation of the standard

Completeness is mostly important to guarantee compatibility with existing HDL code. Once a design has been verified and tested, HDL designers are very reluctant regarding changes to the design, even if it is only about a few minor changes to work around a missing feature in a new synthesis tool.

Correctness is crucial. In some areas this is obvious (such as correct synthesis of basic behavioural models). But it is also crucial for the areas that concern minor details of the standard, such as the exact rules for handling signed expressions, even when the HDL code does not target different synthesis tools. This is because (unlike software source code that is only processed by compilers), in most design flows HDL code is not only processed by the synthesis tool but also by one or more simulators and sometimes even a formal verification tool. It is key for this verification process that all these tools use the same interpretation for the HDL code.

2.3.2 Optimizations

Generally it is hard to give a one-dimensional description of how well a synthesis tool optimizes the design. First of all because not all optimizations are applicable to all designs and all synthesis tasks. Some optimizations work (best) on a coarse-grained level (with complex cells such as adders or multipliers) and others work (best) on a fine-grained level (single bit gates). Some optimizations target area and others target speed. Some work well on large designs while others don't scale well and can only be applied to small designs.

A good tool is capable of applying a wide range of optimizations at different levels of abstraction and gives the designer control over which optimizations are performed (or skipped) and what the optimization goals are.

2.3.3 Technology mapping

Technology mapping is the process of converting the design into a netlist of cells that are available in the target architecture. In an ASIC flow this might be the process-specific cell library provided by the fab. In an FPGA flow this might be LUT cells as well as special function units such as dedicated multipliers. In a coarse-grain flow this might even be more complex special function units.

An open and vendor independent tool is especially of interest if it supports a wide range of different types of target architectures.

2.4 Script-based synthesis flows

A digital design is usually started by implementing a high-level or system-level simulation of the desired function. This description is then manually transformed (or re-implemented) into a synthesizable lower-level description (usually at the behavioural level) and the equivalence of the two representations is verified by simulating both and comparing the simulation results.

Then the synthesizable description is transformed to lower-level representations using a series of tools and the results are again verified using simulation. This process is illustrated in Fig. 2.2.

Fig. 2.2: Typical design flow. Green boxes represent manually created models. Orange boxes represent models generated by synthesis tools.

In this example the System Level Model and the Behavioural Model are both manually written design files. After the equivalence of system level model and behavioural model has been verified, the lower level representations of the design can be generated using synthesis tools. Finally the RTL Model and the Gate-Level Model are verified and the design process is finished.

However, in any real-world design effort there will be multiple iterations for this design process. The reason for this can be the late change of a design requirement or the fact that the analysis of a low-abstraction model (e.g. gate-level timing analysis) revealed that a design change is required in order to meet the design requirements (e.g. maximum possible clock speed).

Whenever the behavioural model or the system level model is changed their equivalence must be re-verified by re-running the simulations and comparing the results. Whenever the behavioural model is changed the synthesis must be re-run and the synthesis results must be re-verified.

In order to guarantee reproducibility it is important to be able to re-run all automatic steps in a design project with a fixed set of settings easily. Because of this, usually all programs used in a synthesis flow can be controlled using scripts. This means that all functions are available via text commands. When such a tool provides a GUI, this is complementary to, and not instead of, a command line interface.

Usually a synthesis flow in an UNIX/Linux environment would be controlled by a shell script that calls all required tools (synthesis and simulation/verification in this example) in the correct order. Each of these tools would be called with a script file containing commands for the respective tool. All settings required for the tool would be provided by these script files so that no manual interaction would be necessary. These script files are considered design sources and should be kept under version control just like the source code of the system level and the behavioural model.

2.5 Methods from compiler design

Some parts of synthesis tools involve problem domains that are traditionally known from compiler design. This section addresses some of these domains.

2.5.1 Lexing and parsing

The best known concepts from compiler design are probably lexing and parsing. These are two methods that together can be used to process complex computer languages easily. [ASU86]

A lexer consumes single characters from the input and generates a stream of lexical tokens that consist of a type and a value. For example the Verilog input `assign foo = bar + 42;` might be translated by the lexer to the list of lexical tokens given in Tab. 2.1.

Table 2.1: Exemplary token list for the statement `assign foo = bar + 42;`

Token-Type	Token-Value
TOK_ASSIGN	-
TOK_IDENTIFIER	"foo"
TOK_EQ	-
TOK_IDENTIFIER	"bar"
TOK_PLUS	-
TOK_NUMBER	42
TOK_SEMICOLON	-

The lexer is usually generated by a lexer generator (e.g. flex) from a description file that is using regular expressions to specify the text pattern that should match the individual tokens.

The lexer is also responsible for skipping ignored characters (such as whitespace outside string constants and comments in the case of Verilog) and converting the original text snippet to a token value.

Note that individual keywords use different token types (instead of a keyword type with different token values). This is because the parser usually can only use the Token-Type to make a decision on the grammatical role of a token.

The parser then transforms the list of tokens into a parse tree that closely resembles the productions from the computer languages grammar. As the lexer, the parser is also typically generated by a code generator (e.g. bison) from a grammar description in Backus-Naur Form (BNF).

Let's consider the following BNF (in Bison syntax):

```

1 assign_stmt: TOK_ASSIGN TOK_IDENTIFIER TOK_EQ expr TOK_SEMICOLON;
2 expr: TOK_IDENTIFIER | TOK_NUMBER | expr TOK_PLUS expr;
```

The parser converts the token list to the parse tree in Fig. 2.3. Note that the parse tree never actually exists as a whole as data structure in memory. Instead the parser calls user-specified code snippets (so-called reduce-functions) for all inner nodes of the parse tree in depth-first order.

In some very simple applications (e.g. code generation for stack machines) it is possible to perform the task at hand directly in the reduce functions. But usually the reduce functions are only used to build an in-memory data structure with the relevant information from the parse tree. This data structure is called an abstract syntax tree (AST).

Fig. 2.3: Example parse tree for the Verilog expression `assign foo = bar + 42;`

The exact format for the abstract syntax tree is application specific (while the format of the parse tree and token list are mostly dictated by the grammar of the language at hand). Figure 2.4 illustrates what an AST for the parse tree in Fig. 2.3 could look like.

Usually the AST is then converted into yet another representation that is more suitable for further processing. In compilers this is often an assembler-like three-address-code intermediate representation. [ASU86]

Fig. 2.4: Example abstract syntax tree for the Verilog expression `assign foo = bar + 42;`

2.5.2 Multi-pass compilation

Complex problems are often best solved when split up into smaller problems. This is certainly true for compilers as well as for synthesis tools. The components responsible for solving the smaller problems can be connected in two different ways: through Single-Pass Pipelining and by using Multiple Passes.

Traditionally a parser and lexer are connected using the pipelined approach: The lexer provides a function that is called by the parser. This function reads data from the input until a complete lexical token has been read. Then this token is returned to the parser. So the lexer does not first generate a complete list of lexical tokens and then pass it to the parser. Instead they run concurrently and the parser can consume tokens as the lexer produces them.

The single-pass pipelining approach has the advantage of lower memory footprint (at no time must the complete design be kept in memory) but has the disadvantage of tighter coupling between the interacting components.

Therefore single-pass pipelining should only be used when the lower memory footprint is required or the components are also conceptually tightly coupled. The latter certainly is the case for a parser and its lexer. But when data is passed between two conceptually loosely coupled components it is often beneficial to use a multi-pass approach.

In the multi-pass approach the first component processes all the data and the result is stored in a in-memory data structure. Then the second component is called with this data. This reduces complexity, as only one component is running at a time. It also improves flexibility as components can be exchanged easier.

Most modern compilers are multi-pass compilers.

2.5.3 Static Single Assignment (SSA) form

In imperative programming (and behavioural HDL design) it is possible to assign the same variable multiple times. This can either mean that the variable is independently used in two different contexts or that the final value of the variable depends on a condition.

The following examples show C code in which one variable is used independently in two different contexts:

```
1 void demo1()
2 {
3     int a = 1;
4     printf("%d\n", a);
5
6     a = 2;
7     printf("%d\n", a);
8 }
```

```
void demo1()
{
    int a = 1;
    printf("%d\n", a);

    int b = 2;
    printf("%d\n", b);
}
```

```
1 void demo2(bool foo)
2 {
3     int a;
4     if (foo) {
5         a = 23;
6         printf("%d\n", a);
7     } else {
8         a = 42;
9         printf("%d\n", a);
10    }
11 }
```

```

void demo2(bool foo)
{
    int a, b;
    if (foo) {
        a = 23;
        printf("%d\n", a);
    } else {
        b = 42;
        printf("%d\n", b);
    }
}

```

In both examples the left version (only variable `a`) and the right version (variables `a` and `b`) are equivalent. Therefore it is desired for further processing to bring the code in an equivalent form for both cases.

In the following example the variable is assigned twice but it cannot be easily replaced by two variables:

```

void demo3(bool foo)
{
    int a = 23
    if (foo)
        a = 42;
    printf("%d\n", a);
}

```

Static single assignment (SSA) form is a representation of imperative code that uses identical representations for the left and right version of demos 1 and 2, but can still represent demo 3. In SSA form each assignment assigns a new variable (usually written with an index). But it also introduces a special Φ -function to merge the different instances of a variable when needed. In C-pseudo-code the demo 3 would be written as follows using SSA form:

```

void demo3(bool foo)
{
    int a_1, a_2, a_3;
    a_1 = 23
    if (foo)
        a_2 = 42;
    a_3 = phi(a_1, a_2);
    printf("%d\n", a_3);
}

```

The Φ -function is usually interpreted as “these variables must be stored in the same memory location” during code generation. Most modern compilers for imperative languages such as C/C++ use SSA form for at least some of its passes as it is very easy to manipulate and analyse.

APPROACH

Yosys is a tool for synthesising (behavioural) Verilog HDL code to target architecture netlists. Yosys aims at a wide range of application domains and thus must be flexible and easy to adapt to new tasks. This chapter covers the general approach followed in the effort to implement this tool.

3.1 Data- and control-flow

The data- and control-flow of a typical synthesis tool is very similar to the data- and control-flow of a typical compiler: different subsystems are called in a predetermined order, each consuming the data generated by the last subsystem and generating the data for the next subsystem (see Fig. 3.1).

Fig. 3.1: General data- and control-flow of a synthesis tool

The first subsystem to be called is usually called a frontend. It does not process the data generated by another subsystem but instead reads the user input—in the case of a HDL synthesis tool, the behavioural HDL code.

The subsystems that consume data from previous subsystems and produce data for the next subsystems (usually in the same or a similar format) are called passes.

The last subsystem that is executed transforms the data generated by the last pass into a suitable output format and writes it to a disk file. This subsystem is usually called the backend.

In Yosys all frontends, passes and backends are directly available as commands in the synthesis script. Thus the user can easily create a custom synthesis flow just by calling passes in the right order in a synthesis script.

3.2 Internal formats in Yosys

Yosys uses two different internal formats. The first is used to store an abstract syntax tree (AST) of a Verilog input file. This format is simply called AST and is generated by the Verilog Frontend. This data structure is consumed by a subsystem called AST Frontend¹. This AST Frontend then generates a design in Yosys' main internal format, the Register-Transfer-Level-Intermediate-Language (RTLIL) representation. It does that by first performing a number of simplifications within the AST representation and then generating RTLIL from the simplified AST data structure.

The RTLIL representation is used by all passes as input and outputs. This has the following advantages over using different representational formats between different passes:

- The passes can be rearranged in a different order and passes can be removed or inserted.
- Passes can simply pass-thru the parts of the design they don't change without the need to convert between formats. In fact Yosys passes output the same data structure they received as input and performs all changes in place.
- All passes use the same interface, thus reducing the effort required to understand a pass when reading the Yosys source code, e.g. when adding additional features.

The RTLIL representation is basically a netlist representation with the following additional features:

- An internal cell library with fixed-function cells to represent RTL datapath and register cells as well as logical gate-level cells (single-bit gates and registers).
- Support for multi-bit values that can use individual bits from wires as well as constant bits to represent coarse-grain netlists.
- Support for basic behavioural constructs (if-then-else structures and multi-case switches with a sensitivity list for updating the outputs).
- Support for multi-port memories.

The use of RTLIL also has the disadvantage of having a very powerful format between all passes, even when doing gate-level synthesis where the more advanced features are not needed. In order to reduce complexity for passes that operate on a low-level representation, these passes check the features used in the input RTLIL and fail to run when unsupported high-level constructs are used. In such cases a pass that transforms the higher-level constructs to lower-level constructs must be called from the synthesis script first.

3.3 Typical use case

The following example script may be used in a synthesis flow to convert the behavioural Verilog code from the input file `design.v` to a gate-level netlist `synth.v` using the cell library described by the Liberty file :

```
1 # read input file to internal representation
2 read_verilog design.v
3
4 # convert high-level behavioral parts ("processes") to d-type flip-flops and muxes
5 proc
6
7 # perform some simple optimizations
8 opt
9
```

(continues on next page)

¹ In Yosys the term pass is only used to refer to commands that operate on the RTLIL data structure.

(continued from previous page)

```
10 # convert high-level memory constructs to d-type flip-flops and multiplexers
11 memory
12
13 # perform some simple optimizations
14 opt
15

A detailed description of the commands available in Yosys can be found in [Command line reference](#).

IMPLEMENTATION OVERVIEW

Yosys is an extensible open source hardware synthesis tool. It is aimed at designers who are looking for an easily accessible, universal, and vendor-independent synthesis tool, as well as scientists who do research in electronic design automation (EDA) and are looking for an open synthesis framework that can be used to test algorithms on complex real-world designs.

Yosys can synthesize a large subset of Verilog 2005 and has been tested with a wide range of real-world designs, including the [OpenRISC 1200 CPU](#), the [openMSP430 CPU](#), the [OpenCores I2C master](#), and the [k68 CPU](#).

As of this writing a Yosys VHDL frontend is in development.

Yosys is written in C++ (using some features from the new C++11 standard). This chapter describes some of the fundamental Yosys data structures. For the sake of simplicity the C++ type names used in the Yosys implementation are used in this chapter, even though the chapter only explains the conceptual idea behind it and can be used as reference to implement a similar system in any language.

4.1 Simplified data flow

[Figure 4.1](#) shows the simplified data flow within Yosys. Rectangles in the figure represent program modules and ellipses internal data structures that are used to exchange design data between the program modules.

Design data is read in using one of the frontend modules. The high-level HDL frontends for Verilog and VHDL code generate an abstract syntax tree (AST) that is then passed to the AST frontend. Note that both HDL frontends use the same AST representation that is powerful enough to cover the Verilog HDL and VHDL language.

The AST Frontend then compiles the AST to Yosys's main internal data format, the RTL Intermediate Language (RTLIL). A more detailed description of this format is given in the next section.

There is also a text representation of the RTLIL data structure that can be parsed using the RTLIL Frontend.

The design data may then be transformed using a series of passes that all operate on the RTLIL representation of the design.

Finally the design in RTLIL representation is converted back to text by one of the backends, namely the Verilog Backend for generating Verilog netlists and the RTLIL Backend for writing the RTLIL data in the same format that is understood by the RTLIL Frontend.

With the exception of the AST Frontend, which is called by the high-level HDL frontends and can't be called directly by the user, all program modules are called by the user (usually using a synthesis script that contains text commands for Yosys).

By combining passes in different ways and/or adding additional passes to Yosys it is possible to adapt Yosys to a wide range of applications. For this to be possible it is key that (1) all passes operate on the same data

structure (RTLIL) and (2) that this data structure is powerful enough to represent the design in different stages of the synthesis.

Fig. 4.1: Yosys simplified data flow (ellipses: data structures, rectangles: program modules)

4.2 The RTL Intermediate Language (RTLIL)

All frontends, passes and backends in Yosys operate on a design in RTLIL representation. The only exception are the high-level frontends that use the AST representation as an intermediate step before generating RTLIL data.

In order to avoid reinventing names for the RTLIL classes, they are simply referred to by their full C++ name, i.e. including the RTLIL:: namespace prefix, in this document.

Figure 4.2 shows a simplified Entity-Relationship Diagram (ER Diagram) of RTLIL. In $1 : N$ relationships the arrow points from the N side to the 1 . For example one RTLIL::Design contains N (zero to many) instances of RTLIL::Module. A two-pointed arrow indicates a $1 : 1$ relationship.

The RTLIL::Design is the root object of the RTLIL data structure. There is always one “current design” in memory which passes operate on, frontends add data to and backends convert to exportable formats. But in some cases passes internally generate additional RTLIL::Design objects. For example when a pass is reading an auxiliary Verilog file such as a cell library, it might create an additional RTLIL::Design object and call the Verilog frontend with this other object to parse the cell library.

There is only one active RTLIL::Design object that is used by all frontends, passes and backends called by the user, e.g. using a synthesis script. The RTLIL::Design then contains zero to many RTLIL::Module objects. This corresponds to modules in Verilog or entities in VHDL. Each module in turn contains objects from three different categories:

Fig. 4.2: Simplified RTLIL Entity-Relationship Diagram

- `RTLIL::Cell` and `RTLIL::Wire` objects represent classical netlist data.
- `RTLIL::Process` objects represent the decision trees (if-then-else statements, etc.) and synchronization declarations (clock signals and sensitivity) from Verilog always and VHDL process blocks.
- `RTLIL::Memory` objects represent addressable memories (arrays).

Usually the output of the synthesis procedure is a netlist, i.e. all `RTLIL::Process` and `RTLIL::Memory` objects must be replaced by `RTLIL::Cell` and `RTLIL::Wire` objects by synthesis passes.

All features of the HDL that cannot be mapped directly to these RTLIL classes must be transformed to an RTLIL-compatible representation by the HDL frontend. This includes Verilog-features such as generate-blocks, loops and parameters.

The following sections contain a more detailed description of the different parts of RTLIL and rationale behind some of the design decisions.

4.2.1 RTLIL identifiers

All identifiers in RTLIL (such as module names, port names, signal names, cell types, etc.) follow the following naming convention: they must either start with a backslash (`\`) or a dollar sign (`$`).

Identifiers starting with a backslash are public visible identifiers. Usually they originate from one of the HDL input files. For example the signal name `\sig42` is most likely a signal that was declared using the name `“sig42”` in an HDL input file. On the other hand the signal name `“$sig42”` is an auto-generated signal name. The backends convert all identifiers that start with a dollar sign to identifiers that do not collide with identifiers that start with a backslash.

This has three advantages:

- First, it is impossible that an auto-generated identifier collides with an identifier that was provided by the user.
- Second, the information about which identifiers were originally provided by the user is always available which can help guide some optimizations. For example the `“opt_rmunused”` tries to preserve signals with a user-provided name but doesn't hesitate to delete signals that have auto-generated names when they just duplicate other signals.

- Third, the delicate job of finding suitable auto-generated public visible names is deferred to one central location. Internally auto-generated names that may hold important information for Yosys developers can be used without disturbing external tools. For example the Verilog backend assigns names in the form `_integer_`.

Whitespace and control characters (any character with an ASCII code 32 or less) are not allowed in RTLIL identifiers; most frontends and backends cannot support these characters in identifiers.

In order to avoid programming errors, the RTLIL data structures check if all identifiers start with either a backslash or a dollar sign, and contain no whitespace or control characters. Violating these rules results in a runtime error.

All RTLIL identifiers are case sensitive.

Some transformations, such as flattening, may have to change identifiers provided by the user to avoid name collisions. When that happens, attribute “hdlname” is attached to the object with the changed identifier. This attribute contains one name (if emitted directly by the frontend, or is a result of disambiguation) or multiple names separated by spaces (if a result of flattening). All names specified in the “hdlname” attribute are public and do not include the leading “.”.

4.2.2 RTLIL::Design and RTLIL::Module

The RTLIL::Design object is basically just a container for RTLIL::Module objects. In addition to a list of RTLIL::Module objects the RTLIL::Design also keeps a list of selected objects, i.e. the objects that passes should operate on. In most cases the whole design is selected and therefore passes operate on the whole design. But this mechanism can be useful for more complex synthesis jobs in which only parts of the design should be affected by certain passes.

Besides the objects shown in the ER diagram in Fig. 4.2 an RTLIL::Module object contains the following additional properties:

- The module name
- A list of attributes
- A list of connections between wires
- An optional frontend callback used to derive parametrized variations of the module

The attributes can be Verilog attributes imported by the Verilog frontend or attributes assigned by passes. They can be used to store additional metadata about modules or just mark them to be used by certain part of the synthesis script but not by others.

Verilog and VHDL both support parametric modules (known as “generic entities” in VHDL). The RTLIL format does not support parametric modules itself. Instead each module contains a callback function into the AST frontend to generate a parametrized variation of the RTLIL::Module as needed. This callback then returns the auto-generated name of the parametrized variation of the module. (A hash over the parameters and the module name is used to prohibit the same parametrized variation from being generated twice. For modules with only a few parameters, a name directly containing all parameters is generated instead of a hash string.)

4.2.3 RTLIL::Cell and RTLIL::Wire

A module contains zero to many RTLIL::Cell and RTLIL::Wire objects. Objects of these types are used to model netlists. Usually the goal of all synthesis efforts is to convert all modules to a state where the functionality of the module is implemented only by cells from a given cell library and wires to connect these cells with each other. Note that module ports are just wires with a special property.

An RTLIL::Wire object has the following properties:

- The wire name
- A list of attributes
- A width (buses are just wires with a width > 1)
- Bus direction (MSB to LSB or vice versa)
- Lowest valid bit index (LSB or MSB depending on bus direction)
- If the wire is a port: port number and direction (input/output/inout)

As with modules, the attributes can be Verilog attributes imported by the Verilog frontend or attributes assigned by passes.

In Yosys, busses (signal vectors) are represented using a single wire object with a width > 1. So Yosys does not convert signal vectors to individual signals. This makes some aspects of RTLIL more complex but enables Yosys to be used for coarse grain synthesis where the cells of the target architecture operate on entire signal vectors instead of single bit wires.

In Verilog and VHDL, busses may have arbitrary bounds, and LSB can have either the lowest or the highest bit index. In RTLIL, bit 0 always corresponds to LSB; however, information from the HDL frontend is preserved so that the bus will be correctly indexed in error messages, backend output, constraint files, etc.

An RTLIL::Cell object has the following properties:

- The cell name and type
- A list of attributes
- A list of parameters (for parametric cells)
- Cell ports and the connections of ports to wires and constants

The connections of ports to wires are coded by assigning an RTLIL::SigSpec to each cell port. The RTLIL::SigSpec data type is described in the next section.

4.2.4 RTLIL::SigSpec

A “signal” is everything that can be applied to a cell port. I.e.

- Any constant value of arbitrary bit-width
1em For example: 1337, 16'b0000010100111001, 1'b1, 1'bx
- All bits of a wire or a selection of bits from a wire
1em For example: mywire, mywire[24], mywire[15:8]
- Concatenations of the above
1em For example: {16'd1337, mywire[15:8]}

The RTLIL::SigSpec data type is used to represent signals. The RTLIL::Cell object contains one RTLIL::SigSpec for each cell port.

In addition, connections between wires are represented using a pair of `RTLIL::SigSpec` objects. Such pairs are needed in different locations. Therefore the type name `RTLIL::SigSig` was defined for such a pair.

4.2.5 RTLIL::Process

When a high-level HDL frontend processes behavioural code it splits it up into data path logic (e.g. the expression $a + b$ is replaced by the output of an adder that takes a and b as inputs) and an `RTLIL::Process` that models the control logic of the behavioural code. Let's consider a simple example:

```

1 module ff_with_en_and_async_reset(clock, reset, enable, d, q);
2   input clock, reset, enable, d;
3   output reg q;
4   always @(posedge clock, posedge reset)
5       if (reset)
6           q <= 0;
7       else if (enable)
8           q <= d;
9 endmodule

```

In this example there is no data path and therefore the `RTLIL::Module` generated by the frontend only contains a few `RTLIL::Wire` objects and an `RTLIL::Process`. The `RTLIL::Process` in RTLIL syntax:

```

1 process $proc$ff_with_en_and_async_reset.v:4$1
2     assign $0\q[0:0] \q
3     switch \reset
4         case 1'1
5             assign $0\q[0:0] 1'0
6         case
7             switch \enable
8                 case 1'1
9                     assign $0\q[0:0] \d
10                case
11                end
12            end
13    sync posedge \clock
14        update \q $0\q[0:0]
15    sync posedge \reset
16        update \q $0\q[0:0]
17 end

```

This `RTLIL::Process` contains two `RTLIL::SyncRule` objects, two `RTLIL::SwitchRule` objects and five `RTLIL::CaseRule` objects. The wire `$0q[0:0]` is an automatically created wire that holds the next value of `\q`. The lines 2...12 describe how `$0q[0:0]` should be calculated. The lines 13...16 describe how the value of `$0q[0:0]` is used to update `\q`.

An `RTLIL::Process` is a container for zero or more `RTLIL::SyncRule` objects and exactly one `RTLIL::CaseRule` object, which is called the root case.

An `RTLIL::SyncRule` object contains an (optional) synchronization condition (signal and edge-type), zero or more assignments (`RTLIL::SigSig`), and zero or more memory writes (`RTLIL::MemWriteAction`). The always synchronization condition is used to break combinatorial loops when a latch should be inferred instead.

An `RTLIL::CaseRule` is a container for zero or more assignments (`RTLIL::SigSig`) and zero or more `RTLIL::SwitchRule` objects. An `RTLIL::SwitchRule` objects is a container for zero or more `RTLIL::CaseRule` objects.

In the above example the lines 2...12 are the root case. Here `$0q[0:0]` is first assigned the old value `\q` as default value (line 2). The root case also contains an `RTLIL::SwitchRule` object (lines 3...12). Such an object is very similar to the C switch statement as it uses a control signal (`\reset` in this case) to determine which of its cases should be active. The `RTLIL::SwitchRule` object then contains one `RTLIL::CaseRule` object per case. In this example there is a case¹ for `\reset == 1` that causes `$0q[0:0]` to be set (lines 4 and 5) and a default case that in turn contains a switch that sets `$0q[0:0]` to the value of `\d` if `\enable` is active (lines 6...11).

A case can specify zero or more compare values that will determine whether it matches. Each of the compare values must be the exact same width as the control signal. When more than one compare value is specified, the case matches if any of them matches the control signal; when zero compare values are specified, the case always matches (i.e. it is the default case).

A switch prioritizes cases from first to last: multiple cases can match, but only the first matched case becomes active. This normally synthesizes to a priority encoder. The `parallel_case` attribute allows passes to assume that no more than one case will match, and `full_case` attribute allows passes to assume that exactly one case will match; if these invariants are ever dynamically violated, the behavior is undefined. These attributes are useful when an invariant invisible to the synthesizer causes the control signal to never take certain bit patterns.

The lines 13...16 then cause `\q` to be updated whenever there is a positive clock edge on `\clock` or `\reset`.

In order to generate such a representation, the language frontend must be able to handle blocking and nonblocking assignments correctly. However, the language frontend does not need to identify the correct type of storage element for the output signal or generate multiplexers for the decision tree. This is done by passes that work on the RTLIL representation. Therefore it is relatively easy to substitute these steps with other algorithms that target different target architectures or perform optimizations or other transformations on the decision trees before further processing them.

One of the first actions performed on a design in RTLIL representation in most synthesis scripts is identifying asynchronous resets. This is usually done using the `proc_arst` pass. This pass transforms the above example to the following `RTLIL::Process`:

```

1  process $proc$ff_with_en_and_async_reset.v:4$1
2      assign $0q[0:0] \q
3      switch \enable
4          case 1'1
5              assign $0q[0:0] \d
6          case
7      end
8      sync posedge \clock
9          update \q $0q[0:0]
10     sync high \reset
11     update \q 1'0
12 end

```

This pass has transformed the outer `RTLIL::SwitchRule` into a modified `RTLIL::SyncRule` object for the `\reset` signal. Further processing converts the `RTLIL::Process` into e.g. a d-type flip-flop with asynchronous reset and a multiplexer for the enable signal:

```

1  cell $adff $procdff$6
2      parameter \ARST_POLARITY 1'1
3      parameter \ARST_VALUE 1'0
4      parameter \CLK_POLARITY 1'1

```

(continues on next page)

¹ The syntax `1'1` in the RTLIL code specifies a constant with a length of one bit (the first “1”), and this bit is a one (the second “1”).

(continued from previous page)

```

5     parameter \WIDTH 1
6     connect \ARST \reset
7     connect \CLK \clock
8     connect \D $0\q[0:0]
9     connect \Q \q
10  end
11  cell $mux $procmux$3
12     parameter \WIDTH 1
13     connect \A \q
14     connect \B \d
15     connect \S \enable
16     connect \Y $0\q[0:0]
17  end

```

Different combinations of passes may yield different results. Note that \$adff and \$mux are internal cell types that still need to be mapped to cell types from the target cell library.

Some passes refuse to operate on modules that still contain RTLIL::Process objects as the presence of these objects in a module increases the complexity. Therefore the passes to translate processes to a netlist of cells are usually called early in a synthesis script. The proc pass calls a series of other passes that together perform this conversion in a way that is suitable for most synthesis tasks.

4.2.6 RTLIL::Memory

For every array (memory) in the HDL code an RTLIL::Memory object is created. A memory object has the following properties:

- The memory name
- A list of attributes
- The width of an addressable word
- The size of the memory in number of words

All read accesses to the memory are transformed to \$memrd cells and all write accesses to \$memwr cells by the language frontend. These cells consist of independent read- and write-ports to the memory. Memory initialization is transformed to \$meminit cells by the language frontend. The \MEMID parameter on these cells is used to link them together and to the RTLIL::Memory object they belong to.

The rationale behind using separate cells for the individual ports versus creating a large multiport memory cell right in the language frontend is that the separate \$memrd and \$memwr cells can be consolidated using resource sharing. As resource sharing is a non-trivial optimization problem where different synthesis tasks can have different requirements it lends itself to do the optimisation in separate passes and merge the RTLIL::Memory objects and \$memrd and \$memwr cells to multiport memory blocks after resource sharing is completed.

The memory pass performs this conversion and can (depending on the options passed to it) transform the memories directly to d-type flip-flops and address logic or yield multiport memory blocks (represented using \$mem cells).

See [Sec. 5.1.5](#) for details about the memory cell types.

4.3 Command interface and synthesis scripts

Yosys reads and processes commands from synthesis scripts, command line arguments and an interactive command prompt. Yosys commands consist of a command name and an optional whitespace separated list of arguments. Commands are terminated using the newline character or a semicolon (;). Empty lines and lines starting with the hash sign (#) are ignored. See [Sec. 3.3](#) for an example synthesis script.

The command help can be used to access the command reference manual.

Most commands can operate not only on the entire design but also specifically on selected parts of the design. For example the command dump will print all selected objects in the current design while dump foobar will only print the module foobar and dump * will print the entire design regardless of the current selection.

```
dump */t:$add %x:+[A] \*/w:\* %i
```

The selection mechanism is very powerful. For example the command above will print all wires that are connected to the \A port of a \$add cell. Detailed documentation of the select framework can be found in the command reference for the `select` command.

4.4 Source tree and build system

The Yosys source tree is organized into the following top-level directories:

- backends/
This directory contains a subdirectory for each of the backend modules.
- frontends/
This directory contains a subdirectory for each of the frontend modules.
- kernel/
This directory contains all the core functionality of Yosys. This includes the functions and definitions for working with the RTLIL data structures (rtlil.h and rtlil.cc), the main() function (driver.cc), the internal framework for generating log messages (log.h and log.cc), the internal framework for registering and calling passes (register.h and register.cc), some core commands that are not really passes (select.cc, show.cc, ...) and a couple of other small utility libraries.
- passes/
This directory contains a subdirectory for each pass or group of passes. For example as of this writing the directory passes/opt/ contains the code for seven passes: opt, opt_expr, opt_muxtree, opt_reduce, opt_rmdff, opt_rmunused and opt_merge.
- techlibs/
This directory contains simulation models and standard implementations for the cells from the internal cell library.
- tests/
This directory contains a couple of test cases. Most of the smaller tests are executed automatically when make test is called. The larger tests must be executed manually. Most of the larger tests require downloading external HDL source code and/or external tools. The tests range from comparing simulation results of the synthesized design to the original sources to logic equivalence checking of entire CPU cores.

The top-level Makefile includes frontends/*/Makefile.inc, passes/*/Makefile.inc and backends/*/Makefile.inc. So when extending Yosys it is enough to create a new directory in frontends/,

passes/ or backends/ with your sources and a Makefile.inc. The Yosys kernel automatically detects all commands linked with Yosys. So it is not needed to add additional commands to a central list of commands.

Good starting points for reading example source code to learn how to write passes are passes/opt/opt_rmdff.cc and passes/opt/opt_merge.cc.

See the top-level README file for a quick Getting Started guide and build instructions. The Yosys build is based solely on Makefiles.

Users of the Qt Creator IDE can generate a QT Creator project file using make qtcreator. Users of the Eclipse IDE can use the “Makefile Project with Existing Code” project type in the Eclipse “New Project” dialog (only available after the CDT plugin has been installed) to create an Eclipse project in order to programming extensions to Yosys or just browse the Yosys code base.

INTERNAL CELL LIBRARY

Most of the passes in Yosys operate on netlists, i.e. they only care about the `RTLIL::Wire` and `RTLIL::Cell` objects in an `RTLIL::Module`. This chapter discusses the cell types used by Yosys to represent a behavioural design internally.

This chapter is split in two parts. In the first part the internal RTL cells are covered. These cells are used to represent the design on a coarse grain level. Like in the original HDL code on this level the cells operate on vectors of signals and complex cells like adders exist. In the second part the internal gate cells are covered. These cells are used to represent the design on a fine-grain gate-level. All cells from this category operate on single bit signals.

5.1 RTL cells

Most of the RTL cells closely resemble the operators available in HDLs such as Verilog or VHDL. Therefore Verilog operators are used in the following sections to define the behaviour of the RTL cells.

Note that all RTL cells have parameters indicating the size of inputs and outputs. When passes modify RTL cells they must always keep the values of these parameters in sync with the size of the signals connected to the inputs and outputs.

Simulation models for the RTL cells can be found in the file `techlibs/common/simlib.v` in the Yosys source tree.

5.1.1 Unary operators

All unary RTL cells have one input port `\A` and one output port `\Y`. They also have the following parameters:

`\A_SIGNED`

Set to a non-zero value if the input `\A` is signed and therefore should be sign-extended when needed.

`\A_WIDTH`

The width of the input port `\A`.

`\Y_WIDTH`

The width of the output port `\Y`.

Table 5.1 lists all cells for unary RTL operators.

Table 5.1: Cell types for unary operators with their corresponding Verilog expressions.

Verilog	Cell Type
<code>Y = ~A</code>	<code>\$not</code>
<code>Y = +A</code>	<code>\$pos</code>
<code>Y = -A</code>	<code>\$neg</code>
<code>Y = &A</code>	<code>\$reduce_and</code>
<code>Y = A</code>	<code>\$reduce_or</code>
<code>Y = ^A</code>	<code>\$reduce_xor</code>
<code>Y = ~^A</code>	<code>\$reduce_xnor</code>
<code>Y = A</code>	<code>\$reduce_bool</code>
<code>Y = !A</code>	<code>\$logic_not</code>

For the unary cells that output a logical value (`$reduce_and`, `$reduce_or`, `$reduce_xor`, `$reduce_xnor`, `$reduce_bool`, `$logic_not`), when the `\Y_WIDTH` parameter is greater than 1, the output is zero-extended, and only the least significant bit varies.

Note that `$reduce_or` and `$reduce_bool` actually represent the same logic function. But the HDL frontends generate them in different situations. A `$reduce_or` cell is generated when the prefix `|` operator is being used. A `$reduce_bool` cell is generated when a bit vector is used as a condition in an `if`-statement or `?:`-expression.

5.1.2 Binary operators

All binary RTL cells have two input ports `\A` and `\B` and one output port `\Y`. They also have the following parameters:

`\A_SIGNED`

Set to a non-zero value if the input `\A` is signed and therefore should be sign-extended when needed.

`\A_WIDTH`

The width of the input port `\A`.

`\B_SIGNED`

Set to a non-zero value if the input `\B` is signed and therefore should be sign-extended when needed.

`\B_WIDTH`

The width of the input port `\B`.

`\Y_WIDTH`

The width of the output port `\Y`.

Table 5.2 lists all cells for binary RTL operators.

Table 5.2: Cell types for binary operators with their corresponding Verilog expressions.

Verilog	Cell Type	Verilog	Cell Type
$Y = A \& B$	\$and	$Y = A < B$	\$lt
$Y = A B$	\$or	$Y = A <= B$	\$le
$Y = A \wedge B$	\$xor	$Y = A == B$	\$eq
$Y = A \sim B$	\$xnor	$Y = A != B$	\$ne
$Y = A \ll B$	\$shl	$Y = A >= B$	\$ge
$Y = A \gg B$	\$shr	$Y = A > B$	\$gt
$Y = A \lll B$	\$sshl	$Y = A + B$	\$add
$Y = A \ggg B$	\$sshr	$Y = A - B$	\$sub
$Y = A \&\& B$	\$logic_and	$Y = A * B$	\$mul
$Y = A B$	\$logic_or	$Y = A / B$	\$div
$Y = A === B$	\$eqx	$Y = A \% B$	\$mod
$Y = A !== B$	\$nex	N/A	\$divfloor
$Y = A ** B$	\$pow	N/A	\$modfloor

The \$shl and \$shr cells implement logical shifts, whereas the \$sshl and \$sshr cells implement arithmetic shifts. The \$shl and \$sshl cells implement the same operation. All four of these cells interpret the second operand as unsigned, and require \B_SIGNED to be zero.

Two additional shift operator cells are available that do not directly correspond to any operator in Verilog, \$shift and \$shiftx. The \$shift cell performs a right logical shift if the second operand is positive (or unsigned), and a left logical shift if it is negative. The \$shiftx cell performs the same operation as the \$shift cell, but the vacated bit positions are filled with undef (x) bits, and corresponds to the Verilog indexed part-select expression.

For the binary cells that output a logical value (\$logic_and, \$logic_or, \$eqx, \$nex, \$lt, \$le, \$eq, \$ne, \$ge, \$gt), when the \Y_WIDTH parameter is greater than 1, the output is zero-extended, and only the least significant bit varies.

Division and modulo cells are available in two rounding modes. The original \$div and \$mod cells are based on truncating division, and correspond to the semantics of the verilog / and % operators. The \$divfloor and \$modfloor cells represent flooring division and flooring modulo, the latter of which is also known as “remainder” in several languages. See Table 5.3 for a side-by-side comparison between the different semantics.

Table 5.3: Comparison between different rounding modes for division and modulo cells.

Division	Result	Truncating		Flooring	
		\$div	\$mod	\$divfloor	\$modfloor
$-10 / 3$	-3.3	-3	-1	-4	2
$10 / -3$	-3.3	-3	1	-4	-2
$-10 / -3$	3.3	3	-1	3	-1
$10 / 3$	3.3	3	1	3	1

5.1.3 Multiplexers

Multiplexers are generated by the Verilog HDL frontend for `?:`-expressions. Multiplexers are also generated by the proc pass to map the decision trees from RTLIL::Process objects to logic.

The simplest multiplexer cell type is `$mux`. Cells of this type have a `\WIDTH` parameter and data inputs `\A` and `\B` and a data output `\Y`, all of the specified width. This cell also has a single bit control input `\S`. If `\S` is 0 the value from the input `\A` is sent to the output, if it is 1 the value from the `\B` input is sent to the output. So the `$mux` cell implements the function $Y = S ? B : A$.

The `$pmux` cell is used to multiplex between many inputs using a one-hot select signal. Cells of this type have a `\WIDTH` and a `\S_WIDTH` parameter and inputs `\A`, `\B`, and `\S` and an output `\Y`. The `\S` input is `\S_WIDTH` bits wide. The `\A` input and the output are both `\WIDTH` bits wide and the `\B` input is `\WIDTH*\S_WIDTH` bits wide. When all bits of `\S` are zero, the value from `\A` input is sent to the output. If the n 'th bit from `\S` is set, the value n 'th `\WIDTH` bits wide slice of the `\B` input is sent to the output. When more than one bit from `\S` is set the output is undefined. Cells of this type are used to model “parallel cases” (defined by using the `parallel_case` attribute or detected by an optimization).

The `$tribuf` cell is used to implement tristate logic. Cells of this type have a `\B` parameter and inputs `\A` and `\EN` and an output `\Y`. The `\A` input and `\Y` output are `\WIDTH` bits wide, and the `\EN` input is one bit wide. When `\EN` is 0, the output is not driven. When `\EN` is 1, the value from `\A` input is sent to the `\Y` output. Therefore, the `$tribuf` cell implements the function $Y = EN ? A : 'bz$.

Behavioural code with cascaded if-then-else- and case-statements usually results in trees of multiplexer cells. Many passes (from various optimizations to FSM extraction) heavily depend on these multiplexer trees to understand dependencies between signals. Therefore optimizations should not break these multiplexer trees (e.g. by replacing a multiplexer between a calculated signal and a constant zero with an `$and` gate).

5.1.4 Registers

SR-type latches are represented by `$sr` cells. These cells have input ports `\SET` and `\CLR` and an output port `\Q`. They have the following parameters:

`\WIDTH`

The width of inputs `\SET` and `\CLR` and output `\Q`.

`\SET_POLARITY`

The set input bits are active-high if this parameter has the value `1'b1` and active-low if this parameter is `1'b0`.

`\CLR_POLARITY`

The reset input bits are active-high if this parameter has the value `1'b1` and active-low if this parameter is `1'b0`.

Both set and reset inputs have separate bits for every output bit. When both the set and reset inputs of an `$sr` cell are active for a given bit index, the reset input takes precedence.

D-type flip-flops are represented by `$dff` cells. These cells have a clock port `\CLK`, an input port `\D` and an output port `\Q`. The following parameters are available for `$dff` cells:

`\WIDTH`

The width of input `\D` and output `\Q`.

`\CLK_POLARITY`

Clock is active on the positive edge if this parameter has the value `1'b1` and on the negative edge if this parameter is `1'b0`.

D-type flip-flops with asynchronous reset are represented by `$adff` cells. As the `$dff` cells they have `\CLK`, `\D` and `\Q` ports. In addition they also have a single-bit `\ARST` input port for the reset pin and the following additional two parameters:

`\ARST_POLARITY`

The asynchronous reset is active-high if this parameter has the value `1'b1` and active-low if this parameter is `1'b0`.

`\ARST_VALUE`

The state of `\Q` will be set to this value when the reset is active.

Usually these cells are generated by the `proc` pass using the information in the designs `RTLIL::Process` objects.

D-type flip-flops with synchronous reset are represented by `$sdff` cells. As the `$dff` cells they have `\CLK`, `\D` and `\Q` ports. In addition they also have a single-bit `\SRST` input port for the reset pin and the following additional two parameters:

`\SRST_POLARITY`

The synchronous reset is active-high if this parameter has the value `1'b1` and active-low if this parameter is `1'b0`.

`\SRST_VALUE`

The state of `\Q` will be set to this value when the reset is active.

Note that the `$adff` and `$sdff` cells can only be used when the reset value is constant.

D-type flip-flops with asynchronous load are represented by `$aldff` cells. As the `$dff` cells they have `\CLK`, `\D` and `\Q` ports. In addition they also have a single-bit `\ALOAD` input port for the async load enable pin, a `\AD` input port with the same width as data for the async load data, and the following additional parameter:

`\ALOAD_POLARITY`

The asynchronous load is active-high if this parameter has the value `1'b1` and active-low if this parameter is `1'b0`.

D-type flip-flops with asynchronous set and reset are represented by `$dffsr` cells. As the `$dff` cells they have `\CLK`, `\D` and `\Q` ports. In addition they also have multi-bit `\SET` and `\CLR` input ports and the corresponding polarity parameters, like `$sr` cells.

D-type flip-flops with enable are represented by `$dffe`, `$adffe`, `$aldffe`, `$dffsre`, `$sdffe`, and `$sdffce` cells, which are enhanced variants of `$dff`, `$adff`, `$aldff`, `$dffsr`, `$sdff` (with reset over enable) and `$sdff` (with enable over reset) cells, respectively. They have the same ports and parameters as their base cell. In addition they also have a single-bit `\EN` input port for the enable pin and the following parameter:

`\EN_POLARITY`

The enable input is active-high if this parameter has the value `1'b1` and active-low if this parameter is `1'b0`.

D-type latches are represented by `$dlatch` cells. These cells have an enable port `\EN`, an input port `\D`, and an output port `\Q`. The following parameters are available for `$dlatch` cells:

`\WIDTH`

The width of input `\D` and output `\Q`.

`\EN_POLARITY`

The enable input is active-high if this parameter has the value `1'b1` and active-low if this parameter is `1'b0`.

The latch is transparent when the `\EN` input is active.

D-type latches with reset are represented by `$adlatch` cells. In addition to `$dlatch` ports and parameters, they also have a single-bit `\ARST` input port for the reset pin and the following additional parameters:

\ARST_POLARITY

The asynchronous reset is active-high if this parameter has the value 1'b1 and active-low if this parameter is 1'b0.

\ARST_VALUE

The state of \Q will be set to this value when the reset is active.

D-type latches with set and reset are represented by \$dlatchsr cells. In addition to \$dlatch ports and parameters, they also have multi-bit \SET and \CLR input ports and the corresponding polarity parameters, like \$sr cells.

5.1.5 Memories

Memories are either represented using RTLIL::Memory objects, \$memrd_v2, \$memwr_v2, and \$meminit_v2 cells, or by \$mem_v2 cells alone.

In the first alternative the RTLIL::Memory objects hold the general metadata for the memory (bit width, size in number of words, etc.) and for each port a \$memrd_v2 (read port) or \$memwr_v2 (write port) cell is created. Having individual cells for read and write ports has the advantage that they can be consolidated using resource sharing passes. In some cases this drastically reduces the number of required ports on the memory cell. In this alternative, memory initialization data is represented by \$meminit_v2 cells, which allow delaying constant folding for initialization addresses and data until after the frontend finishes.

The \$memrd_v2 cells have a clock input \CLK, an enable input \EN, an address input \ADDR, a data output \DATA, an asynchronous reset input \ARST, and a synchronous reset input \SRST. They also have the following parameters:

\MEMID

The name of the RTLIL::Memory object that is associated with this read port.

\ABITS

The number of address bits (width of the \ADDR input port).

\WIDTH

The number of data bits (width of the \DATA output port). Note that this may be a power-of-two multiple of the underlying memory's width – such ports are called wide ports and access an aligned group of cells at once. In this case, the corresponding low bits of \ADDR must be tied to 0.

\CLK_ENABLE

When this parameter is non-zero, the clock is used. Otherwise this read port is asynchronous and the \CLK input is not used.

\CLK_POLARITY

Clock is active on the positive edge if this parameter has the value 1'b1 and on the negative edge if this parameter is 1'b0.

\TRANSPARENCY_MASK

This parameter is a bitmask of write ports that this read port is transparent with. The bits of this parameter are indexed by the write port's \PORTID parameter. Transparency can only be enabled between synchronous ports sharing a clock domain. When transparency is enabled for a given port pair, a read and write to the same address in the same cycle will return the new value. Otherwise the old value is returned.

\COLLISION_X_MASK

This parameter is a bitmask of write ports that have undefined collision behavior with this port. The bits of this parameter are indexed by the write port's \PORTID parameter. This behavior can only be enabled between synchronous ports sharing a clock domain. When undefined collision is enabled for a given port pair, a read and write to the same address in the same cycle will return the undefined (all-X) value. This option is exclusive (for a given port pair) with the transparency option.

\ARST_VALUE

Whenever the \ARST input is asserted, the data output will be reset to this value. Only used for synchronous ports.

\SRST_VALUE

Whenever the \SRST input is synchronously asserted, the data output will be reset to this value. Only used for synchronous ports.

\INIT_VALUE

The initial value of the data output, for synchronous ports.

\CE_OVER_SRST

If this parameter is non-zero, the \SRST input is only recognized when \EN is true. Otherwise, \SRST is recognized regardless of \EN.

The \$memwr_v2 cells have a clock input \CLK, an enable input \EN (one enable bit for each data bit), an address input \ADDR and a data input \DATA. They also have the following parameters:

\MEMID

The name of the RTLIL::Memory object that is associated with this write port.

\ABITS

The number of address bits (width of the \ADDR input port).

\WIDTH

The number of data bits (width of the \DATA output port). Like with \$memrd_v2 cells, the width is allowed to be any power-of-two multiple of memory width, with the corresponding restriction on address.

\CLK_ENABLE

When this parameter is non-zero, the clock is used. Otherwise this write port is asynchronous and the \CLK input is not used.

\CLK_POLARITY

Clock is active on positive edge if this parameter has the value 1'b1 and on the negative edge if this parameter is 1'b0.

\PORTID

An identifier for this write port, used to index write port bit mask parameters.

\PRIORITY_MASK

This parameter is a bitmask of write ports that this write port has priority over in case of writing to the same address. The bits of this parameter are indexed by the other write port's \PORTID parameter. Write ports can only have priority over write ports with lower port ID. When two ports write to the same address and neither has priority over the other, the result is undefined. Priority can only be set between two synchronous ports sharing the same clock domain.

The \$meminit_v2 cells have an address input \ADDR, a data input \DATA, with the width of the \DATA port equal to \WIDTH parameter times \WORDS parameter, and a bit enable mask input \EN with width equal to \WIDTH parameter. All three of the inputs must resolve to a constant for synthesis to succeed.

\MEMID

The name of the RTLIL::Memory object that is associated with this initialization cell.

\ABITS

The number of address bits (width of the \ADDR input port).

\WIDTH

The number of data bits per memory location.

\WORDS

The number of consecutive memory locations initialized by this cell.

\PRIORITY

The cell with the higher integer value in this parameter wins an initialization conflict.

The HDL frontend models a memory using RTLIL::Memory objects and asynchronous \$memrd_v2 and \$memwr_v2 cells. The memory pass (i.e.~its various sub-passes) migrates \$dff cells into the \$memrd_v2 and \$memwr_v2 cells making them synchronous, then converts them to a single \$mem_v2 cell and (optionally) maps this cell type to \$dff cells for the individual words and multiplexer-based address decoders for the read and write interfaces. When the last step is disabled or not possible, a \$mem_v2 cell is left in the design.

The \$mem_v2 cell provides the following parameters:

\MEMID

The name of the original RTLIL::Memory object that became this \$mem_v2 cell.

\SIZE

The number of words in the memory.

\ABITS

The number of address bits.

\WIDTH

The number of data bits per word.

\INIT

The initial memory contents.

\RD_PORTS

The number of read ports on this memory cell.

\RD_WIDE_CONTINUATION

This parameter is \RD_PORTS bits wide, containing a bitmask of “wide continuation” read ports. Such ports are used to represent the extra data bits of wide ports in the combined cell, and must have all control signals identical with the preceding port, except for address, which must have the proper sub-cell address encoded in the low bits.

\RD_CLK_ENABLE

This parameter is \RD_PORTS bits wide, containing a clock enable bit for each read port.

\RD_CLK_POLARITY

This parameter is \RD_PORTS bits wide, containing a clock polarity bit for each read port.

\RD_TRANSPARENCY_MASK

This parameter is \RD_PORTS*\WR_PORTS bits wide, containing a concatenation of all \TRANSPARENCY_MASK values of the original \$memrd_v2 cells.

\RD_COLLISION_X_MASK

This parameter is \RD_PORTS*\WR_PORTS bits wide, containing a concatenation of all \COLLISION_X_MASK values of the original \$memrd_v2 cells.

\RD_CE_OVER_SRST

This parameter is \RD_PORTS bits wide, determining relative synchronous reset and enable priority for each read port.

\RD_INIT_VALUE

This parameter is \RD_PORTS*\WIDTH bits wide, containing the initial value for each synchronous read port.

\RD_ARST_VALUE

This parameter is \RD_PORTS*\WIDTH bits wide, containing the asynchronous reset value for each synchronous read port.

\RD_SRST_VALUE

This parameter is `\RD_PORTS*\WIDTH` bits wide, containing the synchronous reset value for each synchronous read port.

\WR_PORTS

The number of write ports on this memory cell.

\WR_WIDE_CONTINUATION

This parameter is `\WR_PORTS` bits wide, containing a bitmask of “wide continuation” write ports.

\WR_CLK_ENABLE

This parameter is `\WR_PORTS` bits wide, containing a clock enable bit for each write port.

\WR_CLK_POLARITY

This parameter is `\WR_PORTS` bits wide, containing a clock polarity bit for each write port.

\WR_PRIORITY_MASK

This parameter is `\WR_PORTS*\WR_PORTS` bits wide, containing a concatenation of all `\PRIORITY_MASK` values of the original `$memwr_v2` cells.

The `$mem_v2` cell has the following ports:

\RD_CLK

This input is `\RD_PORTS` bits wide, containing all clock signals for the read ports.

\RD_EN

This input is `\RD_PORTS` bits wide, containing all enable signals for the read ports.

\RD_ADDR

This input is `\RD_PORTS*\ABITS` bits wide, containing all address signals for the read ports.

\RD_DATA

This output is `\RD_PORTS*\WIDTH` bits wide, containing all data signals for the read ports.

\RD_ARST

This input is `\RD_PORTS` bits wide, containing all asynchronous reset signals for the read ports.

\RD_SRST

This input is `\RD_PORTS` bits wide, containing all synchronous reset signals for the read ports.

\WR_CLK

This input is `\WR_PORTS` bits wide, containing all clock signals for the write ports.

\WR_EN

This input is `\WR_PORTS*\WIDTH` bits wide, containing all enable signals for the write ports.

\WR_ADDR

This input is `\WR_PORTS*\ABITS` bits wide, containing all address signals for the write ports.

\WR_DATA

This input is `\WR_PORTS*\WIDTH` bits wide, containing all data signals for the write ports.

The `memory_collect` pass can be used to convert discrete `$memrd_v2`, `$memwr_v2`, and `$meminit_v2` cells belonging to the same memory to a single `$mem_v2` cell, whereas the `memory_unpack` pass performs the inverse operation. The `memory_dff` pass can combine asynchronous memory ports that are fed by or feeding registers into synchronous memory ports. The `memory_bram` pass can be used to recognize `$mem_v2` cells that can be implemented with a block RAM resource on an FPGA. The `memory_map` pass can be used to implement `$mem_v2` cells as basic logic: word-wide DFFs and address decoders.

5.1.6 Finite state machines

Add a brief description of the `$fsm` cell type.

5.1.7 Specify rules

Add information about `$specify2`, `$specify3`, and `$specrule` cells.

5.1.8 Formal verification cells

Add information about `$assert`, `$assume`, `$live`, `$fair`, `$cover`, `$equiv`, `$initstate`, `$anyconst`, `$anyseq`, `$anyinit`, `$allconst`, `$allseq` cells.

Add information about `$ff` and `$_FF_` cells.

5.2 Gates

For gate level logic networks, fixed function single bit cells are used that do not provide any parameters.

Simulation models for these cells can be found in the file `techlibs/common/simcells.v` in the Yosys source tree.

Table 5.4: Cell types for gate level logic networks (main list)

Verilog	Cell Type
<code>Y = A</code>	<code>\$_BUF_</code>
<code>Y = ~A</code>	<code>\$_NOT_</code>
<code>Y = A & B</code>	<code>\$_AND_</code>
<code>Y = ~(A & B)</code>	<code>\$_NAND_</code>
<code>Y = A & ~B</code>	<code>\$_ANDNOT_</code>
<code>Y = A B</code>	<code>\$_OR_</code>
<code>Y = ~(A B)</code>	<code>\$_NOR_</code>
<code>Y = A ~B</code>	<code>\$_ORNOT_</code>
<code>Y = A ^ B</code>	<code>\$_XOR_</code>
<code>Y = ~(A ^ B)</code>	<code>\$_XNOR_</code>
<code>Y = ~((A & B) C)</code>	<code>\$_AOI3_</code>
<code>Y = ~((A B) & C)</code>	<code>\$_OAI3_</code>
<code>Y = ~((A & B) (C & D))</code>	<code>\$_AOI4_</code>
<code>Y = ~((A B) & (C D))</code>	<code>\$_OAI4_</code>
<code>Y = S ? B : A</code>	<code>\$_MUX_</code>
<code>Y = ~(S ? B : A)</code>	<code>\$_NMUX_</code>
(see below)	<code>\$_MUX4_</code>
(see below)	<code>\$_MUX8_</code>
(see below)	<code>\$_MUX16_</code>
<code>Y = EN ? A : 1'bz</code>	<code>\$_TBUF_</code>
<code>always @(negedge C) Q <= D</code>	<code>\$_DFF_N_</code>
<code>always @(posedge C) Q <= D</code>	<code>\$_DFF_P_</code>
<code>always @* if (!E) Q <= D</code>	<code>\$_DLATCH_N_</code>
<code>always @* if (E) Q <= D</code>	<code>\$_DLATCH_P_</code>

Tables 5.4, 5.6, 5.5, 5.7, 5.8, 5.9, 5.10, 5.11 and 5.12 list all cell types used for gate level logic. The cell types `$ _BUF _`, `$ _NOT _`, `$ _AND _`, `$ _NAND _`, `$ _ANDNOT _`, `$ _OR _`, `$ _NOR _`, `$ _ORNOT _`, `$ _XOR _`, `$ _XNOR _`, `$ _AOI3 _`, `$ _OAI3 _`, `$ _AOI4 _`, `$ _OAI4 _`, `$ _MUX _`, `$ _MUX4 _`, `$ _MUX8 _`, `$ _MUX16 _` and `$ _NMUX _` are used to model combinatorial logic. The cell type `$ _TBUF _` is used to model tristate logic.

The `$ _MUX4 _`, `$ _MUX8 _` and `$ _MUX16 _` cells are used to model wide muxes, and correspond to the following Verilog code:

```
// $ _MUX4 _
assign Y = T ? (S ? D : C) :
           (S ? B : A);

// $ _MUX8 _
assign Y = U ? T ? (S ? H : G) :
           (S ? F : E) :
           T ? (S ? D : C) :
           (S ? B : A);

// $ _MUX16 _
assign Y = V ? U ? T ? (S ? P : O) :
           (S ? N : M) :
           T ? (S ? L : K) :
           (S ? J : I) :
           U ? T ? (S ? H : G) :
           (S ? F : E) :
           T ? (S ? D : C) :
           (S ? B : A);
```

The cell types `$ _DFF _N _` and `$ _DFF _P _` represent d-type flip-flops.

The cell types `$ _DFFE _[NP] [NP] _` implement d-type flip-flops with enable. The values in the table for these cell types relate to the following Verilog code template.

```
always @(CLK_EDGE C)
    if (EN == EN_LVL)
```

(continues on next page)

(continued from previous page)

```
Q <= D;
```

The cell types `$_DFF_[NP][NP][01]_` implement d-type flip-flops with asynchronous reset. The values in the table for these cell types relate to the following Verilog code template, where `RST_EDGE` is `posedge` if `RST_LVL` if 1, and `negedge` otherwise.

```
always @(CLK_EDGE C, RST_EDGE R)
    if (R == RST_LVL)
        Q <= RST_VAL;
    else
        Q <= D;
```

The cell types `$_SDFF_[NP][NP][01]_` implement d-type flip-flops with synchronous reset. The values in the table for these cell types relate to the following Verilog code template:

```
always @(CLK_EDGE C)
    if (R == RST_LVL)
        Q <= RST_VAL;
    else
        Q <= D;
```

The cell types `$_DFFE_[NP][NP][01][NP]_` implement d-type flip-flops with asynchronous reset and enable. The values in the table for these cell types relate to the following Verilog code template, where `RST_EDGE` is `posedge` if `RST_LVL` if 1, and `negedge` otherwise.

```
always @(CLK_EDGE C, RST_EDGE R)
    if (R == RST_LVL)
        Q <= RST_VAL;
    else if (EN == EN_LVL)
        Q <= D;
```

The cell types `$_SDFFE_[NP][NP][01][NP]_` implement d-type flip-flops with synchronous reset and enable, with reset having priority over enable. The values in the table for these cell types relate to the following Verilog code template:

```
always @(CLK_EDGE C)
    if (R == RST_LVL)
        Q <= RST_VAL;
    else if (EN == EN_LVL)
        Q <= D;
```

The cell types `$_SDFFCE_[NP][NP][01][NP]_` implement d-type flip-flops with synchronous reset and enable, with enable having priority over reset. The values in the table for these cell types relate to the following Verilog code template:

```
always @(CLK_EDGE C)
    if (EN == EN_LVL)
        if (R == RST_LVL)
            Q <= RST_VAL;
        else
            Q <= D;
```

The cell types `$_DFFSR_[NP][NP][NP]_` implement d-type flip-flops with asynchronous set and reset. The values in the table for these cell types relate to the following Verilog code template, where `RST_EDGE` is

posedge if RST_LVL if 1, negedge otherwise, and SET_EDGE is posedge if SET_LVL if 1, negedge otherwise.

```
always @(CLK_EDGE C, RST_EDGE R, SET_EDGE S)
    if (R == RST_LVL)
        Q <= 0;
    else if (S == SET_LVL)
        Q <= 1;
    else
        Q <= D;
```

The cell types `$_DFFSRE_[NP][NP][NP][NP]_` implement d-type flip-flops with asynchronous set and reset and enable. The values in the table for these cell types relate to the following Verilog code template, where RST_EDGE is posedge if RST_LVL if 1, negedge otherwise, and SET_EDGE is posedge if SET_LVL if 1, negedge otherwise.

```
always @(CLK_EDGE C, RST_EDGE R, SET_EDGE S)
    if (R == RST_LVL)
        Q <= 0;
    else if (S == SET_LVL)
        Q <= 1;
    else if (E == EN_LVL)
        Q <= D;
```

The cell types `$_DLATCH_N_` and `$_DLATCH_P_` represent d-type latches.

The cell types `$_DLATCH_[NP][NP][01]_` implement d-type latches with reset. The values in the table for these cell types relate to the following Verilog code template:

```
always @*
    if (R == RST_LVL)
        Q <= RST_VAL;
    else if (E == EN_LVL)
        Q <= D;
```

The cell types `$_DLATCHSR_[NP][NP][NP]_` implement d-type latches with set and reset. The values in the table for these cell types relate to the following Verilog code template:

```
always @*
    if (R == RST_LVL)
        Q <= 0;
    else if (S == SET_LVL)
        Q <= 1;
    else if (E == EN_LVL)
        Q <= D;
```

The cell types `$_SR_[NP][NP]_` implement sr-type latches. The values in the table for these cell types relate to the following Verilog code template:

```
always @*
    if (R == RST_LVL)
        Q <= 0;
    else if (S == SET_LVL)
        Q <= 1;
```

In most cases gate level logic networks are created from RTL networks using the techmap pass. The flip-flop cells from the gate level logic network can be mapped to physical flip-flop cells from a Liberty file using the

dfflibmap pass. The combinatorial logic cells can be mapped to physical cells from a Liberty file via ABC using the abc pass.

Add information about `$slice` and `$concat` cells.

Add information about `$lut` and `$sop` cells.

Add information about `$alu`, `$macc`, `$fa`, and `$lcu` cells.

PROGRAMMING YOSYS EXTENSIONS

This chapter contains some bits and pieces of information about programming yosys extensions. Also consult the section on programming in the “Yosys Presentation” (can be downloaded from the Yosys website as PDF) and don’t be afraid to ask questions on the YosysHQ Slack.

6.1 Guidelines

The guidelines directory contains notes on various aspects of Yosys development. The files `GettingStarted` and `CodingStyle` may be of particular interest, and are reproduced here.

Listing 6.1: `guidelines/GettingStarted`

```
Getting Started
=====

Outline of a Yosys command
-----

Here is a the C++ code for a "hello_world" Yosys command (hello.cc):

    #include "kernel/yosys.h"

    USING_YOSYS_NAMESPACE
    PRIVATE_NAMESPACE_BEGIN

    struct HelloWorldPass : public Pass {
        HelloWorldPass() : Pass("hello_world") { }
        void execute(vector<string>, Design*) override {
            log("Hello World!\n");
        }
    } HelloWorldPass;

    PRIVATE_NAMESPACE_END

This can be built into a Yosys module using the following command:

    yosys-config --exec --cxx --cxxflags --ldflags -o hello.so -shared hello.cc --
    ↪ldlibs
```

(continues on next page)

(continued from previous page)

Or short:

```
yosys-config --build hello.so hello.cc
```

And then executed using the following command:

```
yosys -m hello.so -p hello_world
```

Yosys Data Structures

Here is a short list of data structures that you should make yourself familiar with before you write C++ code for Yosys. The following data structures are all defined when "kernel/yosys.h" is included and USING_YOSYS_NAMESPACE is used.

1. Yosys Container Classes

Yosys uses `dict<K, T>` and `pool<T>` as main container classes. `dict<K, T>` is essentially a replacement for `std::unordered_map<K, T>` and `pool<T>` is a replacement for `std::unordered_set<T>`. The main characteristics are:

- `dict<K, T>` and `pool<T>` are about 2x faster than the std containers
- references to elements in a `dict<K, T>` or `pool<T>` are invalidated by insert and remove operations (similar to `std::vector<T>` on `push_back()`).
- some iterators are invalidated by `erase()`. specifically, iterators that have not passed the erased element yet are invalidated. (`erase()` itself returns valid iterator to the next element.)
- no iterators are invalidated by `insert()`. elements are inserted at `begin()`. i.e. only a new iterator that starts at `begin()` will see the inserted elements.
- the method `.count(key, iterator)` is like `.count(key)` but only considers elements that can be reached via the iterator.
- iterators can be compared. `it1 < it2` means that the position of `t2` can be reached via `t1` but not vice versa.
- the method `.sort()` can be used to sort the elements in the container the container stays sorted until elements are added or removed.
- `dict<K, T>` and `pool<T>` will have the same order of iteration across all compilers, standard libraries and architectures.

In addition to `dict<K, T>` and `pool<T>` there is also an `idict<K>` that creates a bijective map from `K` to the integers. For example:

```
idict<string, 42> si;
log("%d\n", si("hello"));    // will print 42
```

(continues on next page)

(continued from previous page)

```

log("%d\n", si("world"));      // will print 43
log("%d\n", si.at("world"));   // will print 43
log("%d\n", si.at("dummy"));   // will throw exception
log("%s\n", si[42].c_str());   // will print hello
log("%s\n", si[43].c_str());   // will print world
log("%s\n", si[44].c_str());   // will throw exception

```

It is not possible to remove elements from an idict.

Finally mfp<K> implements a merge-find set data structure (aka. disjoint-set or union-find) over the type K ("mfp" = merge-find-promote).

2. Standard STL data types

In Yosys we use `std::vector<T>` and `std::string` whenever applicable. When `dict<K, T>` and `pool<T>` are not suitable then `std::map<K, T>` and `std::set<T>` are used instead.

The types `std::vector<T>` and `std::string` are also available as `vector<T>` and `string` in the Yosys namespace.

3. RTLIL objects

The current design (essentially a collection of modules, each defined by a netlist) is stored in memory using RTLIL object (declared in `kernel/rtlil.h`, automatically included by `kernel/yosys.h`). You should glance over at least the declarations for the following types in `kernel/rtlil.h`:

```

RTLIL::IdString
    This is a handle for an identifier (e.g. cell or wire name).
    It feels a lot like a std::string, but is only a single int
    in size. (The actual string is stored in a global lookup
    table.)

RTLIL::SigBit
    A single signal bit. I.e. either a constant state (0, 1,
    x, z) or a single bit from a wire.

RTLIL::SigSpec
    Essentially a vector of SigBits.

RTLIL::Wire
RTLIL::Cell
    The building blocks of the netlist in a module.

RTLIL::Module
RTLIL::Design
    The module is a container with connected cells and wires
    in it. The design is a container with modules in it.

```

All these types are also available without the `RTLIL::` prefix in the Yosys namespace.

(continues on next page)

(continued from previous page)

4. SigMap and other Helper Classes

There are a couple of additional helper classes that are in wide use in Yosys. Most importantly there is SigMap (declared in kernel/sigtools.h).

When a design has many wires in it that are connected to each other, then a single signal bit can have multiple valid names. The SigMap object can be used to map SigSpecs or SigBits to unique SigSpecs and SigBits that consistently only use one wire from such a group of connected wires. For example:

```
SigBit a = module->addWire(NEW_ID);
SigBit b = module->addWire(NEW_ID);
module->connect(a, b);

log("%d\n", a == b); // will print 0

SigMap sigmap(module);
log("%d\n", sigmap(a) == sigmap(b)); // will print 1
```

Using the RTLIL Netlist Format

In the RTLIL netlist format the cell ports contain SigSpecs that point to the Wires. There are no references in the other direction. This has two direct consequences:

- (1) It is very easy to go from cells to wires but hard to go in the other way.
- (2) There is no danger in removing cells from the netlists, but removing wires can break the netlist format when there are still references to the wire somewhere in the netlist.

The solution to (1) is easy: Create custom indexes that allow you to make fast lookups for the wire-to-cell direction. You can either use existing generic index structures to do that (such as the ModIndex class) or write your own index. For many application it is simplest to construct a custom index. For example:

```
SigMap sigmap(module);
dict<SigBit, Cell*> sigbit_to_driver_index;

for (auto cell : module->cells())
    for (auto &conn : cell->connections())
        if (cell->output(conn.first))
            for (auto bit : sigmap(conn.second))
                sigbit_to_driver_index[bit] = cell;
```

Regarding (2): There is a general theme in Yosys that you don't remove wires from the design. You can rename them, unconnect them, but you do not actually remove the Wire object from the module. Instead you let the "clean" command take care

(continues on next page)

(continued from previous page)

of the dangling wires. On the other hand it is safe to remove cells (as long as you make sure this does not invalidate a custom index you are using in your code).

Example Code

The following yosys commands are a good starting point if you are looking for examples of how to use the Yosys API:

```
docs/source/CHAPTER_Prog/stubnets.cc
manual/PRESENTATION_Prog/my_cmd.cc
```

Script Passes

The ScriptPass base class can be used to implement passes that just call other passes, like a script. Examples for such passes are:

```
techlibs/common/prep.cc
techlibs/common/synth.cc
```

In some cases it is easier to implement such a pass as regular pass, for example when ScriptPass doesn't provide the type of flow control desired. (But many of the script passes in Yosys that don't use ScriptPass simply predate the ScriptPass base class.) Examples for such passes are:

```
passes/opt/opt.cc
passes/proc/proc.cc
```

Whether they use the ScriptPass base-class or not, a pass should always either call other passes without doing any non-trivial work itself, or should implement a non-trivial algorithm but not call any other passes. The reason for this is that this helps containing complexity in individual passes and simplifies debugging the entire system.

Exceptions to this rule should be rare and limited to cases where calling other passes is optional and only happens when requested by the user (such as for example ``techmap -autoproc``), or where it is about commands that are "top-level commands" in their own right, not components to be used in regular synthesis flows (such as the ``bugpoint`` command).

A pass that would "naturally" call other passes and also do some work itself should be re-written in one of two ways:

- 1) It could be re-written as script pass with the parts that are not calls to other passes factored out into individual new passes. Usually in those cases the new sub passes share the same prefix as the top-level script pass.
- 2) It could be re-written so that it already expects the design in a certain state, expecting the calling script to set up this state before calling the

(continues on next page)

(continued from previous page)

pass in questions.

Many back-ends are examples for the 2nd approach. For example, ``write_aiger`` does not convert the design into AIG representation, but expects the design to be already in this form, and prints an ``Unsupported cell type`` error message otherwise.

Notes on the existing codebase

For historical reasons not all parts of Yosys adhere to the current coding style. When adding code to existing parts of the system, adhere to this guide for the new code instead of trying to mimic the style of the surrounding code.

Listing 6.2: guidelines/CodingStyle

Coding Style

=====

Formatting of code

- Yosys code is using tabs for indentation. Tabs are 8 characters.
- A continuation of a statement in the following line is indented by two additional tabs.
- Lines are as long as you want them to be. A good rule of thumb is to break lines at about column 150.
- Opening braces can be put on the same or next line as the statement opening the block (if, switch, for, while, do). Put the opening brace on its own line for larger blocks, especially blocks that contains blank lines.
- Otherwise stick to the Linux Kernel Coding Style:
<https://www.kernel.org/doc/Documentation/CodingStyle>

C++ Language

Yosys is written in C++11.

In general Yosys uses `"int"` instead of `"size_t"`. To avoid compiler warnings for implicit type casts, always use `"GetSize(foo)"` instead of `"foo.size()"`. (`GetSize()` is defined in `kernel/yosys.h`)

Use range-based for loops whenever applicable.

6.2 The “stubsnets” example module

The following is the complete code of the “stubsnets” example module. It is included in the Yosys source distribution as docs/source/CHAPTER_Prog/stubnets.cc.

Listing 6.3: docs/source/CHAPTER_Prog/stubnets.cc

```

THE VERILOG AND AST FRONTENDS

This chapter provides an overview of the implementation of the Yosys Verilog and AST frontends. The Verilog frontend reads Verilog-2005 code and creates an abstract syntax tree (AST) representation of the input. This AST representation is then passed to the AST frontend that converts it to RTLIL data, as illustrated in Fig. 7.1.

Fig. 7.1: Simplified Verilog to RTLIL data flow

7.1 Transforming Verilog to AST

The Verilog frontend converts the Verilog sources to an internal AST representation that closely resembles the structure of the original Verilog code. The Verilog frontend consists of three components, the Preprocessor, the Lexer and the Parser.

The source code to the Verilog frontend can be found in `frontends/verilog/` in the Yosys source tree.

7.1.1 The Verilog preprocessor

The Verilog preprocessor scans over the Verilog source code and interprets some of the Verilog compiler directives such as ``include`, ``define` and ``ifdef`.

It is implemented as a C++ function that is passed a file descriptor as input and returns the pre-processed Verilog code as a `std::string`.

The source code to the Verilog Preprocessor can be found in `frontends/verilog/preproc.cc` in the Yosys source tree.

7.1.2 The Verilog lexer

The Verilog Lexer is written using the lexer generator `flex`. Its source code can be found in `frontends/verilog/verilog_lexer.l` in the Yosys source tree. The lexer does little more than identifying all keywords and literals recognised by the Yosys Verilog frontend.

The lexer keeps track of the current location in the Verilog source code using some global variables. These variables are used by the constructor of AST nodes to annotate each node with the source code location it originated from.

Finally the lexer identifies and handles special comments such as `“// synopsys translate_off”` and `“/ / synopsys full_case”`. (It is recommended to use ``ifdef` constructs instead of the Synopsys `translate_on/off` comments and attributes such as `(* full_case *)` over `“// synopsys full_case”` whenever possible.)

7.1.3 The Verilog parser

The Verilog Parser is written using the parser generator `bison`. Its source code can be found in `frontends/verilog/verilog_parser.y` in the Yosys source tree.

It generates an AST using the `AST::AstNode` data structure defined in `frontends/ast/ast.h`. An `AST::AstNode` object has the following properties:

Table 7.1: AST node types with their corresponding Verilog constructs.

AST Node Type	Corresponding Verilog Construct
<code>AST_NONE</code>	This Node type should never be used.
<code>AST_DESIGN</code>	This node type is used for the top node of the AST tree. It has no corresponding Verilog construct.
<code>AST_MODULE</code> , <code>AST_TASK</code> , <code>AST_FUNCTION</code>	<code>module</code> , <code>task</code> and <code>function</code>
<code>AST_WIRE</code>	<code>input</code> , <code>output</code> , <code>wire</code> , <code>reg</code> and <code>integer</code>
<code>AST_MEMORY</code>	Verilog Arrays

continues on next page

Table 7.1 – continued from previous page

AST_AUTOWIRE	Created by the simplifier when an undeclared signal name is used.
AST_PARAMETER, AST_LOCALPARAM	parameter and localparam
AST_PARASET	Parameter set in cell instantiation
AST_ARGUMENT	Port connection in cell instantiation
AST_RANGE	Bit-Index in a signal or element index in array
AST_CONSTANT	A literal value
AST_CELLTYPE	The type of cell in cell instantiation
AST_IDENTIFIER	An Identifier (signal name in expression or cell/task/etc. name in other contexts)
AST_PREFIX	Construct an identifier in the form <prefix>[<index>].<suffix> (used only in advanced generate constructs)
AST_FCALL, AST_TCALL	Call to function or task
AST_TO_SIGNED, AST_TO_UNSIGNED	The \$signed() and \$unsigned() functions
AST_CONCAT, AST_REPLICATE	The {...} and {...{...}} operators
AST_BIT_NOT, AST_BIT_AND, AST_BIT_OR, AST_BIT_XOR, AST_BIT_XNOR	The bitwise operators ~, &, , ^ and ~^
AST_REDUCE_AND, AST_REDUCE_OR, AST_REDUCE_XOR, AST_REDUCE_XNOR	The unary reduction operators ~, &, , ^ and ~^
AST_REDUCE_BOOL	Conversion from multi-bit value to boolean value (equivalent to AST_REDUCE_OR)
AST_SHIFT_LEFT, AST_SHIFT_RIGHT, AST_SHIFT_SLEFT, AST_SHIFT_SRIGHT	The shift operators <<, >>, <<< and >>>
AST_LT, AST_LE, AST_EQ, AST_NE, AST_GE, AST_GT	The relational operators <, <=, ==, !=, >= and >
AST_ADD, AST_SUB, AST_MUL, AST_DIV, AST_MOD, AST_POW	The binary operators +, -, *, /, % and **
AST_POS, AST_NEG	The prefix operators + and -
AST_LOGIC_AND, AST_LOGIC_OR, AST_LOGIC_NOT	The logic operators &&, and !
AST_TERNARY	The ternary ?:- operator
AST_MEMRD, AST_MEMWR	Read and write memories. These nodes are generated by the AST simplifier for writes/reads to/from Verilog arrays.
AST_ASSIGN	An assign statement
AST_CELL	A cell instantiation
AST_PRIMITIVE	A primitive cell (and, nand, or , etc.)
AST_ALWAYS, AST_INITIAL	Verilog always- and initial- blocks
AST_BLOCK	A begin-end -block
AST_ASSIGN_EQ, AST_ASSIGN_LE	Blocking (=) and nonblocking (<=) assignments within an always- or initial- block
AST_CASE, AST_COND, AST_DEFAULT	The case (if) statements, conditions within a case and the default case respectively
AST_FOR	A for-loop with an always- or initial- block
AST_GENVAR, AST_GENBLOCK, AST_GENFOR, AST_GENIF	The genvar and generate keywords and for and if within a generate block.
AST_POSEDGE, AST_NEGEDGE, AST_EDGE	Event conditions for always blocks.

- The node type

This enum (`AST::AstNodeType`) specifies the role of the node. [Table 7.1](#) contains a list of all node types.

- The child nodes

This is a list of pointers to all children in the abstract syntax tree.

- Attributes

As almost every AST node might have Verilog attributes assigned to it, the `AST::AstNode` has direct support for attributes. Note that the attribute values are again AST nodes.

- Node content

Each node might have additional content data. A series of member variables exist to hold such data. For example the member `std::string str` can hold a string value and is used e.g. in the `AST_IDENTIFIER` node type to store the identifier name.

- Source code location

Each `AST::AstNode` is automatically annotated with the current source code location by the `AST::AstNode` constructor. It is stored in the `std::string filename` and `int linenum` member variables.

The `AST::AstNode` constructor can be called with up to two child nodes that are automatically added to the list of child nodes for the new object. This simplifies the creation of AST nodes for simple expressions a bit. For example the bison code for parsing multiplications:

```
1 basic_expr '*' attr basic_expr {  
2     $$ = new AstNode(AST_MUL, $1, $4);  
3     append_attr($$, $3);  
4 } |
```

The generated AST data structure is then passed directly to the AST frontend that performs the actual conversion to RTLIL.

Note that the Yosys command `read_verilog` provides the options `-yydebug` and `-dump_ast` that can be used to print the parse tree or abstract syntax tree respectively.

7.2 Transforming AST to RTLIL

The AST Frontend converts a set of modules in AST representation to modules in RTLIL representation and adds them to the current design. This is done in two steps: simplification and RTLIL generation.

The source code to the AST frontend can be found in `frontends/ast/` in the Yosys source tree.

7.2.1 AST simplification

A full-featured AST is too complex to be transformed into RTLIL directly. Therefore it must first be brought into a simpler form. This is done by calling the `AST::AstNode::simplify()` method of all `AST_MODULE` nodes in the AST. This initiates a recursive process that performs the following transformations on the AST data structure:

- Inline all task and function calls.
- Evaluate all `generate`-statements and unroll all `for`-loops.
- Perform const folding where it is necessary (e.g. in the value part of `AST_PARAMETER`, `AST_LOCALPARAM`, `AST_PARASET` and `AST_RANGE` nodes).

- Replace `AST_PRIMITIVE` nodes with appropriate `AST_ASSIGN` nodes.
- Replace dynamic bit ranges in the left-hand-side of assignments with `AST_CASE` nodes with `AST_COND` children for each possible case.
- Detect array access patterns that are too complicated for the `RTLIL::Memory` abstraction and replace them with a set of signals and cases for all reads and/or writes.
- Otherwise replace array accesses with `AST_MEMRD` and `AST_MEMWR` nodes.

In addition to these transformations, the simplifier also annotates the AST with additional information that is needed for the RTLIL generator, namely:

- All ranges (width of signals and bit selections) are not only const folded but (when a constant value is found) are also written to member variables in the `AST_RANGE` node.
- All identifiers are resolved and all `AST_IDENTIFIER` nodes are annotated with a pointer to the AST node that contains the declaration of the identifier. If no declaration has been found, an `AST_AUTOWIRE` node is created and used for the annotation.

This produces an AST that is fairly easy to convert to the RTLIL format.

7.2.2 Generating RTLIL

After AST simplification, the `AST::AstNode::genRTLIL()` method of each `AST_MODULE` node in the AST is called. This initiates a recursive process that generates equivalent RTLIL data for the AST data.

The `AST::AstNode::genRTLIL()` method returns an `RTLIL::SigSpec` structure. For nodes that represent expressions (operators, constants, signals, etc.), the cells needed to implement the calculation described by the expression are created and the resulting signal is returned. That way it is easy to generate the circuits for large expressions using depth-first recursion. For nodes that do not represent an expression (such as `AST_CELL`), the corresponding circuit is generated and an empty `RTLIL::SigSpec` is returned.

7.3 Synthesizing Verilog always blocks

For behavioural Verilog code (code utilizing `always`- and `initial`-blocks) it is necessary to also generate `RTLIL::Process` objects. This is done in the following way:

Whenever `AST::AstNode::genRTLIL()` encounters an `always`- or `initial`-block, it creates an instance of `AST_INTERNAL::ProcessGenerator`. This object then generates the `RTLIL::Process` object for the block. It also calls `AST::AstNode::genRTLIL()` for all right-hand-side expressions contained within the block.

First the `AST_INTERNAL::ProcessGenerator` creates a list of all signals assigned within the block. It then creates a set of temporary signals using the naming scheme `$<number> \<original_name>` for each of the assigned signals.

Then an `RTLIL::Process` is created that assigns all intermediate values for each left-hand-side signal to the temporary signal in its `RTLIL::CaseRule`/`RTLIL::SwitchRule` tree.

Finally a `RTLIL::SyncRule` is created for the `RTLIL::Process` that assigns the temporary signals for the final values to the actual signals.

A process may also contain memory writes. A `RTLIL::MemWriteAction` is created for each of them.

Calls to `AST::AstNode::genRTLIL()` are generated for right hand sides as needed. When blocking assignments are used, `AST::AstNode::genRTLIL()` is configured using global variables to use the temporary signals that hold the correct intermediate values whenever one of the previously assigned signals is used in an expression.

Unfortunately the generation of a correct RTLIL::CaseRule/RTLIL::SwitchRule tree for behavioural code is a non-trivial task. The AST frontend solves the problem using the approach described on the following pages. The following example illustrates what the algorithm is supposed to do. Consider the following Verilog code:

```

1  always @(posedge clock) begin
2      out1 = in1;
3      if (in2)
4          out1 = !out1;
5      out2 <= out1;
6      if (in3)
7          out2 <= out2;
8      if (in4)
9          if (in5)
10             out3 <= in6;
11             else
12                 out3 <= in7;
13      out1 = out1 ^ out2;
14  end

```

This is translated by the Verilog and AST frontends into the following RTLIL code (attributes, cell parameters and wire declarations not included):

```

1  cell $logic_not $logic_not$<input>:4$2
2      connect \A \in1
3      connect \Y $logic_not$<input>:4$2_Y
4  end
5  cell $xor $xor$<input>:13$3
6      connect \A $1\out1[0:0]
7      connect \B \out2
8      connect \Y $xor$<input>:13$3_Y
9  end
10 process $proc$<input>:1$1
11     assign $0\out3[0:0] \out3
12     assign $0\out2[0:0] $1\out1[0:0]
13     assign $0\out1[0:0] $xor$<input>:13$3_Y
14     switch \in2
15         case 1'1
16             assign $1\out1[0:0] $logic_not$<input>:4$2_Y
17         case
18             assign $1\out1[0:0] \in1
19     end
20     switch \in3
21         case 1'1
22             assign $0\out2[0:0] \out2
23         case
24     end
25     switch \in4
26         case 1'1
27             switch \in5
28                 case 1'1
29                     assign $0\out3[0:0] \in6
30                 case
31                     assign $0\out3[0:0] \in7

```

(continues on next page)

(continued from previous page)

```

32     end
33     case
34 end
35 sync posedge \clock
36     update \out1 $0\out1[0:0]
37     update \out2 $0\out2[0:0]
38     update \out3 $0\out3[0:0]
39 end

```

Note that the two operators are translated into separate cells outside the generated process. The signal `out1` is assigned using blocking assignments and therefore `out1` has been replaced with a different signal in all expressions after the initial assignment. The signal `out2` is assigned using nonblocking assignments and therefore is not substituted on the right-hand-side expressions.

The `RTLIL::CaseRule/RTLIL::SwitchRule` tree must be interpreted the following way:

- On each case level (the body of the process is the root case), first the actions on this level are evaluated and then the switches within the case are evaluated. (Note that the last assignment on line 13 of the Verilog code has been moved to the beginning of the RTLIL process to line 13 of the RTLIL listing.)

I.e. the special cases deeper in the switch hierarchy override the defaults on the upper levels. The assignments in lines 12 and 22 of the RTLIL code serve as an example for this.

Note that in contrast to this, the order within the `RTLIL::SwitchRule` objects within a `RTLIL::CaseRule` is preserved with respect to the original AST and Verilog code.

- The whole `RTLIL::CaseRule/RTLIL::SwitchRule` tree describes an asynchronous circuit. I.e. the decision tree formed by the switches can be seen independently for each assigned signal. Whenever one assigned signal changes, all signals that depend on the changed signals are to be updated. For example the assignments in lines 16 and 18 in the RTLIL code in fact influence the assignment in line 12, even though they are in the “wrong order”.

The only synchronous part of the process is in the `RTLIL::SyncRule` object generated at line 35 in the RTLIL code. The sync rule is the only part of the process where the original signals are assigned. The synchronization event from the original Verilog code has been translated into the synchronization type (posedge) and signal (`\clock`) for the `RTLIL::SyncRule` object. In the case of this simple example the `RTLIL::SyncRule` object is later simply transformed into a set of d-type flip-flops and the `RTLIL::CaseRule/RTLIL::SwitchRule` tree to a decision tree using multiplexers.

In more complex examples (e.g. asynchronous resets) the part of the `RTLIL::CaseRule/RTLIL::SwitchRule` tree that describes the asynchronous reset must first be transformed to the correct `RTLIL::SyncRule` objects. This is done by the `proc_adff` pass.

7.3.1 The ProcessGenerator algorithm

The `AST_INTERNAL::ProcessGenerator` uses the following internal state variables:

- `subst_rvalue_from` and `subst_rvalue_to`
These two variables hold the replacement pattern that should be used by `AST::AstNode::genRTLIL()` for signals with blocking assignments. After initialization of `AST_INTERNAL::ProcessGenerator` these two variables are empty.
- `subst_lvalue_from` and `subst_lvalue_to`
These two variables contain the mapping from left-hand-side signals (`\<name>`) to the current temporary signal for the same thing (initially `$0\<name>`).

- **current_case**

A pointer to a `RTLIL::CaseRule` object. Initially this is the root case of the generated `RTLIL::Process`.

As the algorithm runs these variables are continuously modified as well as pushed to the stack and later restored to their earlier values by popping from the stack.

On startup the `ProcessGenerator` generates a new `RTLIL::Process` object with an empty root case and initializes its state variables as described above. Then the `RTLIL::SyncRule` objects are created using the synchronization events from the `AST_ALWAYS` node and the initial values of `subst_lvalue_from` and `subst_lvalue_to`. Then the AST for this process is evaluated recursively.

During this recursive evaluation, three different relevant types of AST nodes can be discovered: `AST_ASSIGN_LE` (nonblocking assignments), `AST_ASSIGN_EQ` (blocking assignments) and `AST_CASE` (if or case statement).

Handling of nonblocking assignments

When an `AST_ASSIGN_LE` node is discovered, the following actions are performed by the `ProcessGenerator`:

- The left-hand-side is evaluated using `AST::AstNode::genRTLIL()` and mapped to a temporary signal name using `subst_lvalue_from` and `subst_lvalue_to`.
- The right-hand-side is evaluated using `AST::AstNode::genRTLIL()`. For this call, the values of `subst_rvalue_from` and `subst_rvalue_to` are used to map blocking-assigned signals correctly.
- Remove all assignments to the same left-hand-side as this assignment from the `current_case` and all cases within it.
- Add the new assignment to the `current_case`.

Handling of blocking assignments

When an `AST_ASSIGN_EQ` node is discovered, the following actions are performed by the `ProcessGenerator`:

- Perform all the steps that would be performed for a nonblocking assignment (see above).
- Remove the found left-hand-side (before lvalue mapping) from `subst_rvalue_from` and also remove the respective bits from `subst_rvalue_to`.
- Append the found left-hand-side (before lvalue mapping) to `subst_rvalue_from` and append the found right-hand-side to `subst_rvalue_to`.

Handling of cases and if-statements

When an `AST_CASE` node is discovered, the following actions are performed by the `ProcessGenerator`:

- The values of `subst_rvalue_from`, `subst_rvalue_to`, `subst_lvalue_from` and `subst_lvalue_to` are pushed to the stack.
- A new `RTLIL::SwitchRule` object is generated, the selection expression is evaluated using `AST::AstNode::genRTLIL()` (with the use of `subst_rvalue_from` and `subst_rvalue_to`) and added to the `RTLIL::SwitchRule` object and the object is added to the `current_case`.
- All lvalues assigned to within the `AST_CASE` node using blocking assignments are collected and saved in the local variable `this_case_eq_lvalue`.

- New temporary signals are generated for all signals in `this_case_eq_lvalue` and stored in `this_case_eq_ltemp`.
- The signals in `this_case_eq_lvalue` are mapped using `subst_rvalue_from` and `subst_rvalue_to` and the resulting set of signals is stored in `this_case_eq_rvalue`.

Then the following steps are performed for each `AST_COND` node within the `AST_CASE` node:

- Set `subst_rvalue_from`, `subst_rvalue_to`, `subst_lvalue_from` and `subst_lvalue_to` to the values that have been pushed to the stack.
- Remove `this_case_eq_lvalue` from `subst_lvalue_from/subst_lvalue_to`.
- Append `this_case_eq_lvalue` to `subst_lvalue_from` and append `this_case_eq_ltemp` to `subst_lvalue_to`.
- Push the value of `current_case`.
- Create a new `RTLIL::CaseRule`. Set `current_case` to the new object and add the new object to the `RTLIL::SwitchRule` created above.
- Add an assignment from `this_case_eq_rvalue` to `this_case_eq_ltemp` to the new `current_case`.
- Evaluate the compare value for this case using `AST::AstNode::genRTLIL()` (with the use of `subst_rvalue_from` and `subst_rvalue_to`) modify the new `current_case` accordingly.
- Recursion into the children of the `AST_COND` node.
- Restore `current_case` by popping the old value from the stack.

Finally the following steps are performed:

- The values of `subst_rvalue_from`, `subst_rvalue_to`, `subst_lvalue_from` and `subst_lvalue_to` are popped from the stack.
- The signals from `this_case_eq_lvalue` are removed from the `subst_rvalue_from/subst_rvalue_to`-pair.
- The value of `this_case_eq_lvalue` is appended to `subst_rvalue_from` and the value of `this_case_eq_ltemp` is appended to `subst_rvalue_to`.
- Map the signals in `this_case_eq_lvalue` using `subst_lvalue_from/subst_lvalue_to`.
- Remove all assignments to signals in `this_case_eq_lvalue` in `current_case` and all cases within it.
- Add an assignment from `this_case_eq_ltemp` to `this_case_eq_lvalue` to `current_case`.

Further analysis of the algorithm for cases and if-statements

With respect to nonblocking assignments the algorithm is easy: later assignments invalidate earlier assignments. For each signal assigned using nonblocking assignments exactly one temporary variable is generated (with the `$0`-prefix) and this variable is used for all assignments of the variable.

Note how all the `_eq`-variables become empty when no blocking assignments are used and many of the steps in the algorithm can then be ignored as a result of this.

For a variable with blocking assignments the algorithm shows the following behaviour: First a new temporary variable is created. This new temporary variable is then registered as the assignment target for all assignments for this variable within the cases for this `AST_CASE` node. Then for each case the new temporary variable is first assigned the old temporary variable. This assignment is overwritten if the variable is actually assigned in this case and is kept as a default value otherwise.

This yields an `RTLIL::CaseRule` that assigns the new temporary variable in all branches. So when all cases have been processed a final assignment is added to the containing block that assigns the new temporary variable to the old one. Note how this step always overrides a previous assignment to the old temporary variable. Other than nonblocking assignments, the old assignment could still have an effect somewhere in the design, as there have been calls to `AST::AstNode::genRTLIL()` with a `subst_rvalue_from/subst_rvalue_to`-tuple that contained the right-hand-side of the old assignment.

7.3.2 The proc pass

The `ProcessGenerator` converts a behavioural model in AST representation to a behavioural model in `RTLIL::Process` representation. The actual conversion from a behavioural model to an RTL representation is performed by the proc pass and the passes it launches:

- `proc_clean` and `proc_rmdead`
These two passes just clean up the `RTLIL::Process` structure. The `proc_clean` pass removes empty parts (eg. empty assignments) from the process and `proc_rmdead` detects and removes unreachable branches from the process's decision trees.
- `proc_arst`
This pass detects processes that describe d-type flip-flops with asynchronous resets and rewrites the process to better reflect what they are modelling: Before this pass, an asynchronous reset has two edge-sensitive sync rules and one top-level for the reset path. After this pass the sync rule for the reset is level-sensitive and the top-level has been removed.
- `proc_mux`
This pass converts the `/-`-tree to a tree of multiplexers per written signal. After this, the structure only contains the `s` that describe the output registers.
- `proc_dff`
This pass replaces the `s` to d-type flip-flops (with asynchronous resets if necessary).
- `proc_dff`
This pass replaces the `s` with `$memwr` cells.
- `proc_clean`
A final call to `proc_clean` removes the now empty objects.

Performing these last processing steps in passes instead of in the Verilog frontend has two important benefits:

First it improves the transparency of the process. Everything that happens in a separate pass is easier to debug, as the `RTLIL` data structures can be easily investigated before and after each of the steps.

Second it improves flexibility. This scheme can easily be extended to support other types of storage-elements, such as sr-latches or d-latches, without having to extend the actual Verilog frontend.

7.4 Synthesizing Verilog arrays

Add some information on the generation of `$memrd` and `$memwr` cells and how they are processed in the memory pass.

7.5 Synthesizing parametric designs

Add some information on the `RTLIL::Module::derive()` method and how it is used to synthesize parametric modules via the hierarchy pass.

OPTIMIZATIONS

Yosys employs a number of optimizations to generate better and cleaner results. This chapter outlines these optimizations.

8.1 Simple optimizations

The Yosys pass `opt` runs a number of simple optimizations. This includes removing unused signals and cells and const folding. It is recommended to run this pass after each major step in the synthesis script. At the time of this writing the `opt` pass executes the following passes that each perform a simple optimization:

- Once at the beginning of `opt`:
 - `opt_expr`
 - `opt_merge -nomux`
- Repeat until result is stable:
 - `opt_muxtree`
 - `opt_reduce`
 - `opt_merge`
 - `opt_rmdff`
 - `opt_clean`
 - `opt_expr`

The following section describes each of the `opt__` passes.

8.1.1 The `opt_expr` pass

This pass performs const folding on the internal combinational cell types described in [Chap. 5](#). This means a cell with all constant inputs is replaced with the constant value this cell drives. In some cases this pass can also optimize cells with some constant inputs.

Table 8.1: Const folding rules for `$_AND_` cells as used in `opt_expr`.

A-Input	B-Input	Replacement
any	0	0
0	any	0
1	1	1
X/Z	X/Z	X
1	X/Z	X
X/Z	1	X
any	X/Z	0
X/Z	any	0
<i>a</i>	1	<i>a</i>
1	<i>b</i>	<i>b</i>

Table 8.1 shows the replacement rules used for optimizing an `$_AND_` gate. The first three rules implement the obvious const folding rules. Note that ‘any’ might include dynamic values calculated by other parts of the circuit. The following three lines propagate undef (X) states. These are the only three cases in which it is allowed to propagate an undef according to Sec. 5.1.10 of IEEE Std. 1364-2005 [A+06].

The next two lines assume the value 0 for undef states. These two rules are only used if no other substitutions are possible in the current module. If other substitutions are possible they are performed first, in the hope that the ‘any’ will change to an undef value or a 1 and therefore the output can be set to undef.

The last two lines simply replace an `$_AND_` gate with one constant-1 input with a buffer.

Besides this basic const folding the `opt_expr` pass can replace 1-bit wide `$eq` and `$ne` cells with buffers or not-gates if one input is constant.

The `opt_expr` pass is very conservative regarding optimizing `$mux` cells, as these cells are often used to model decision-trees and breaking these trees can interfere with other optimizations.

8.1.2 The `opt_muxtree` pass

This pass optimizes trees of multiplexer cells by analyzing the select inputs. Consider the following simple example:

```
1 module uut(a, y); input a; output [1:0] y = a ? (a ? 1 : 2) : 3; endmodule
```

The output can never be 2, as this would require `a` to be 1 for the outer multiplexer and 0 for the inner multiplexer. The `opt_muxtree` pass detects this contradiction and replaces the inner multiplexer with a constant 1, yielding the logic for `y = a ? 1 : 3`.

8.1.3 The `opt_reduce` pass

This is a simple optimization pass that identifies and consolidates identical input bits to `$reduce_and` and `$reduce_or` cells. It also sorts the input bits to ease identification of shareable `$reduce_and` and `$reduce_or` cells in other passes.

This pass also identifies and consolidates identical inputs to multiplexer cells. In this case the new shared select bit is driven using a `$reduce_or` cell that combines the original select bits.

Lastly this pass consolidates trees of `$reduce_and` cells and trees of `$reduce_or` cells to single large `$reduce_and` or `$reduce_or` cells.

These three simple optimizations are performed in a loop until a stable result is produced.

8.1.4 The `opt_rmdff` pass

This pass identifies single-bit d-type flip-flops (`$_DFF_`, `$dff`, and `$adff` cells) with a constant data input and replaces them with a constant driver.

8.1.5 The `opt_clean` pass

This pass identifies unused signals and cells and removes them from the design. It also creates an `\unused_bits` attribute on wires with unused bits. This attribute can be used for debugging or by other optimization passes.

8.1.6 The `opt_merge` pass

This pass performs trivial resource sharing. This means that this pass identifies cells with identical inputs and replaces them with a single instance of the cell.

The option `-nomux` can be used to disable resource sharing for multiplexer cells (`$mux` and `$pmux`). This can be useful as it prevents multiplexer trees to be merged, which might prevent `opt_muxtree` to identify possible optimizations.

8.2 FSM extraction and encoding

The `fsm` pass performs finite-state-machine (FSM) extraction and recoding. The `fsm` pass simply executes the following other passes:

- Identify and extract FSMs:
 - `fsm_detect`
 - `fsm_extract`
- Basic optimizations:
 - `fsm_opt`
 - `opt_clean`
 - `fsm_opt`
- Expanding to nearby gate-logic (if called with `-expand`):
 - `fsm_expand`
 - `opt_clean`
 - `fsm_opt`
- Re-code FSM states (unless called with `-norecode`):
 - `fsm_recode`
- Print information about FSMs:
 - `fsm_info`
- Export FSMs in KISS2 file format (if called with `-export`):
 - `fsm_export`
- Map FSMs to RTL cells (unless called with `-nomap`):

– fsm_map

The fsm_detect pass identifies FSM state registers and marks them using the `\fsm_encoding = "auto"` attribute. The fsm_extract extracts all FSMs marked using the `\fsm_encoding` attribute (unless `\fsm_encoding` is set to “none”) and replaces the corresponding RTL cells with a \$fsm cell. All other fsm_ passes operate on these \$fsm cells. The fsm_map call finally replaces the \$fsm cells with RTL cells.

Note that these optimizations operate on an RTL netlist. I.e. the fsm pass should be executed after the proc pass has transformed all RTLIL::Process objects to RTL cells.

The algorithms used for FSM detection and extraction are influenced by a more general reported technique [STGR10].

8.2.1 FSM detection

The fsm_detect pass identifies FSM state registers. It sets the `\fsm_encoding = "auto"` attribute on any (multi-bit) wire that matches the following description:

- Does not already have the `\fsm_encoding` attribute.
- Is not an output of the containing module.
- Is driven by single \$dff or \$adff cell.
- The \D-Input of this \$dff or \$adff cell is driven by a multiplexer tree that only has constants or the old state value on its leaves.
- The state value is only used in the said multiplexer tree or by simple relational cells that compare the state value to a constant (usually \$eq cells).

This heuristic has proven to work very well. It is possible to overwrite it by setting `\fsm_encoding = "auto"` on registers that should be considered FSM state registers and setting `\fsm_encoding = "none"` on registers that match the above criteria but should not be considered FSM state registers.

Note however that marking state registers with `\fsm_encoding` that are not suitable for FSM recoding can cause synthesis to fail or produce invalid results.

8.2.2 FSM extraction

The fsm_extract pass operates on all state signals marked with the `(\fsm_encoding != "none")` attribute. For each state signal the following information is determined:

- The state registers
- The asynchronous reset state if the state registers use asynchronous reset
- All states and the control input signals used in the state transition functions
- The control output signals calculated from the state signals and control inputs
- A table of all state transitions and corresponding control inputs- and outputs

The state registers (and asynchronous reset state, if applicable) is simply determined by identifying the driver for the state signal.

From there the \$mux-tree driving the state register inputs is recursively traversed. All select inputs are control signals and the leaves of the \$mux-tree are the states. The algorithm fails if a non-constant leaf that is not the state signal itself is found.

The list of control outputs is initialized with the bits from the state signal. It is then extended by adding all values that are calculated by cells that compare the state signal with a constant value.

In most cases this will cover all uses of the state register, thus rendering the state encoding arbitrary. If however a design uses e.g. a single bit of the state value to drive a control output directly, this bit of the state signal will be transformed to a control output of the same value.

Finally, a transition table for the FSM is generated. This is done by using the `ConstEval` C++ helper class (defined in `kernel/consteval.h`) that can be used to evaluate parts of the design. The `ConstEval` class can be asked to calculate a given set of result signals using a set of signal-value assignments. It can also be passed a list of stop-signals that abort the `ConstEval` algorithm if the value of a stop-signal is needed in order to calculate the result signals.

The `fsm_extract` pass uses the `ConstEval` class in the following way to create a transition table. For each state:

1. Create a `ConstEval` object for the module containing the FSM
2. Add all control inputs to the list of stop signals
3. Set the state signal to the current state
4. Try to evaluate the next state and control output
5. If step 4 was not successful:
 - Recursively goto step 4 with the offending stop-signal set to 0.
 - Recursively goto step 4 with the offending stop-signal set to 1.
6. If step 4 was successful: Emit transition

Finally a `$fsm` cell is created with the generated transition table and added to the module. This new cell is connected to the control signals and the old drivers for the control outputs are disconnected.

8.2.3 FSM optimization

The `fsm_opt` pass performs basic optimizations on `$fsm` cells (not including state recoding). The following optimizations are performed (in this order):

- Unused control outputs are removed from the `$fsm` cell. The attribute `\unused_bits` (that is usually set by the `opt_clean` pass) is used to determine which control outputs are unused.
- Control inputs that are connected to the same driver are merged.
- When a control input is driven by a control output, the control input is removed and the transition table altered to give the same performance without the external feedback path.
- Entries in the transition table that yield the same output and only differ in the value of a single control input bit are merged and the different bit is removed from the sensitivity list (turned into a don't-care bit).
- Constant inputs are removed and the transition table is altered to give an unchanged behaviour.
- Unused inputs are removed.

8.2.4 FSM recoding

The `fsm_recode` pass assigns new bit pattern to the states. Usually this also implies a change in the width of the state signal. At the moment of this writing only one-hot encoding with all-zero for the reset state is supported.

The `fsm_recode` pass can also write a text file with the changes performed by it that can be used when verifying designs synthesized by Yosys using Synopsys Formality .

8.3 Logic optimization

Yosys can perform multi-level combinational logic optimization on gate-level netlists using the external program ABC . The `abc` pass extracts the combinational gate-level parts of the design, passes it through ABC, and re-integrates the results. The `abc` pass can also be used to perform other operations using ABC, such as technology mapping (see [Sec 9.3](#) for details).

TECHNOLOGY MAPPING

Previous chapters outlined how HDL code is transformed into an RTL netlist. The RTL netlist is still based on abstract coarse-grain cell types like arbitrary width adders and even multipliers. This chapter covers how an RTL netlist is transformed into a functionally equivalent netlist utilizing the cell types available in the target architecture.

Technology mapping is often performed in two phases. In the first phase RTL cells are mapped to an internal library of single-bit cells (see [Sec. 5.2](#)). In the second phase this netlist of internal gate types is transformed to a netlist of gates from the target technology library.

When the target architecture provides coarse-grain cells (such as block ram or ALUs), these must be mapped to directly form the RTL netlist, as information on the coarse-grain structure of the design is lost when it is mapped to bit-width gate types.

9.1 Cell substitution

The simplest form of technology mapping is cell substitution, as performed by the techmap pass. This pass, when provided with a Verilog file that implements the RTL cell types using simpler cells, simply replaces the RTL cells with the provided implementation.

When no map file is provided, techmap uses a built-in map file that maps the Yosys RTL cell types to the internal gate library used by Yosys. The curious reader may find this map file as `techlibs/common/techmap.v` in the Yosys source tree.

Additional features have been added to techmap to allow for conditional mapping of cells (see [techmap - generic technology mapper](#)). This can for example be useful if the target architecture supports hardware multipliers for certain bit-widths but not for others.

A usual synthesis flow would first use the techmap pass to directly map some RTL cells to coarse-grain cells provided by the target architecture (if any) and then use techmap with the built-in default file to map the remaining RTL cells to gate logic.

9.2 Subcircuit substitution

Sometimes the target architecture provides cells that are more powerful than the RTL cells used by Yosys. For example a cell in the target architecture that can calculate the absolute-difference of two numbers does not match any single RTL cell type but only combinations of cells.

For these cases Yosys provides the extract pass that can match a given set of modules against a design and identify the portions of the design that are identical (i.e. isomorphic subcircuits) to any of the given modules. These matched subcircuits are then replaced by instances of the given modules.

The extract pass also finds basic variations of the given modules, such as swapped inputs on commutative cell types.

In addition to this the extract pass also has limited support for frequent subcircuit mining, i.e. the process of finding recurring subcircuits in the design. This has a few applications, including the design of new coarse-grain architectures [GW13].

The hard algorithmic work done by the extract pass (solving the isomorphic subcircuit problem and frequent subcircuit mining) is performed using the SubCircuit library that can also be used stand-alone without Yosys (see *SubCircuit*).

9.3 Gate-level technology mapping

On the gate-level the target architecture is usually described by a “Liberty file”. The Liberty file format is an industry standard format that can be used to describe the behaviour and other properties of standard library cells .

Mapping a design utilizing the Yosys internal gate library (e.g. as a result of mapping it to this representation using the techmap pass) is performed in two phases.

First the register cells must be mapped to the registers that are available on the target architectures. The target architecture might not provide all variations of d-type flip-flops with positive and negative clock edge, high-active and low-active asynchronous set and/or reset, etc. Therefore the process of mapping the registers might add additional inverters to the design and thus it is important to map the register cells first.

Mapping of the register cells may be performed by using the dfflibmap pass. This pass expects a Liberty file as argument (using the -liberty option) and only uses the register cells from the Liberty file.

Secondly the combinational logic must be mapped to the target architecture. This is done using the external program ABC via the abc pass by using the -liberty option to the pass. Note that in this case only the combinatorial cells are used from the cell library.

Occasionally Liberty files contain trade secrets (such as sensitive timing information) that cannot be shared freely. This complicates processes such as reporting bugs in the tools involved. When the information in the Liberty file used by Yosys and ABC are not part of the sensitive information, the additional tool *yosys-filterlib* (see *yosys-filterlib*) can be used to strip the sensitive information from the Liberty file.

MEMORY MAPPING

Documentation for the Yosys `memory_libmap` memory mapper. Note that not all supported patterns are included in this document, of particular note is that combinations of multiple patterns should generally work. For example, *Write port with byte enables* could be used in conjunction with any of the simple dual port (SDP) models. In general if a hardware memory definition does not support a given configuration, additional logic will be instantiated to guarantee behaviour is consistent with simulation.

See also: [passes/memory/memlib.md](#)

10.1 Additional notes

10.1.1 Memory kind selection

The memory inference code will automatically pick target memory primitive based on memory geometry and features used. Depending on the target, there can be up to four memory primitive classes available for selection:

- FF RAM (aka logic): no hardware primitive used, memory lowered to a bunch of FFs and multiplexers
 - Can handle arbitrary number of write ports, as long as all write ports are in the same clock domain
 - Can handle arbitrary number and kind of read ports
- LUT RAM (aka distributed RAM): uses LUT storage as RAM
 - Supported on most FPGAs (with notable exception of ice40)
 - Usually has one synchronous write port, one or more asynchronous read ports
 - Small
 - Will never be used for ROMs (lowering to plain LUTs is always better)
- Block RAM: dedicated memory tiles
 - Supported on basically all FPGAs
 - Supports only synchronous reads
 - Two ports with separate clocks
 - Usually supports true dual port (with notable exception of ice40 that only supports SDP)
 - Usually supports asymmetric memories and per-byte write enables
 - Several kilobits in size
- Huge RAM:

- Only supported on several targets:
 - * Some Xilinx UltraScale devices (UltraRAM)
 - Two ports, both with mutually exclusive synchronous read and write
 - Single clock
 - Initial data must be all-0
 - * Some ice40 devices (SPRAM)
 - Single port with mutually exclusive synchronous read and write
 - Does not support initial data
 - * Nexus (large RAM)
 - Two ports, both with mutually exclusive synchronous read and write
 - Single clock
- Will not be automatically selected by memory inference code, needs explicit opt-in via `ram_style` attribute

In general, you can expect the automatic selection process to work roughly like this:

- If any read port is asynchronous, only LUT RAM (or FF RAM) can be used.
- If there is more than one write port, only block RAM can be used, and this needs to be a hardware-supported true dual port pattern
 - ... unless all write ports are in the same clock domain, in which case FF RAM can also be used, but this is generally not what you want for anything but really small memories
- Otherwise, either FF RAM, LUT RAM, or block RAM will be used, depending on memory size

This process can be overridden by attaching a `ram_style` attribute to the memory:

- (`* ram_style = "logic" *`) selects FF RAM
- (`* ram_style = "distributed" *`) selects LUT RAM
- (`* ram_style = "block" *`) selects block RAM
- (`* ram_style = "huge" *`) selects huge RAM

It is an error if this override cannot be realized for the given target.

Many alternate spellings of the attribute are also accepted, for compatibility with other software.

10.1.2 Initial data

Most FPGA targets support initializing all kinds of memory to user-provided values. If explicit initialization is not used the initial memory value is undefined. Initial data can be provided by either initial statements writing memory cells one by one of `$readmemh` or `$readmemb` system tasks. For an example pattern, see *Synchronous read port with initial value*.

10.1.3 Write port with byte enables

- Byte enables can be used with any supported pattern
- To ensure that multiple writes will be merged into one port, they need to have disjoint bit ranges, have the same address, and the same clock
- Any write enable granularity will be accepted (down to per-bit write enables), but using smaller granularity than natively supported by the target is very likely to be inefficient (eg. using 4-bit bytes on ECP5 will result in either padding the bytes with 5 dummy bits to native 9-bit units or splitting the RAM into two block RAMs)

```
reg [31 : 0] mem [2**ADDR_WIDTH - 1 : 0];

always @(posedge clk) begin
    if (write_enable[0])
        mem[write_addr][7:0] <= write_data[7:0];
    if (write_enable[1])
        mem[write_addr][15:8] <= write_data[15:8];
    if (write_enable[2])
        mem[write_addr][23:16] <= write_data[23:16];
    if (write_enable[3])
        mem[write_addr][31:24] <= write_data[31:24];
    if (read_enable)
        read_data <= mem[read_addr];
end
```

10.2 Simple dual port (SDP) memory patterns

10.2.1 Asynchronous-read SDP

- This will result in LUT RAM on supported targets

```
reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];
always @(posedge clk)
    if (write_enable)
        mem[write_addr] <= write_data;
assign read_data = mem[read_addr];
```

10.2.2 Synchronous SDP with clock domain crossing

- Will result in block RAM or LUT RAM depending on size
- No behavior guarantees in case of simultaneous read and write to the same address

```
reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];

always @(posedge write_clk) begin
    if (write_enable)
        mem[write_addr] <= write_data;
end
```

(continues on next page)

(continued from previous page)

```

always @(posedge read_clk) begin
    if (read_enable)
        read_data <= mem[read_addr];
end

```

10.2.3 Synchronous SDP read first

- The read and write parts can be in the same or different processes.
- Will result in block RAM or LUT RAM depending on size
- As long as the same clock is used for both, yosys will ensure read-first behavior. This may require extra circuitry on some targets for block RAM. If this is not necessary, use one of the patterns below.

```

reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];

always @(posedge clk) begin
    if (write_enable)
        mem[write_addr] <= write_data;
    if (read_enable)
        read_data <= mem[read_addr];
end

```

10.2.4 Synchronous SDP with undefined collision behavior

- Like above, but the read value is undefined when read and write ports target the same address in the same cycle

```

reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];

always @(posedge clk) begin
    if (write_enable)
        mem[write_addr] <= write_data;

    if (read_enable) begin
        read_data <= mem[read_addr];

        // this if block
        if (write_enable && read_addr == write_addr)
            read_data <= 'x;
    end
end

```

- Or below, using the no_rw_check attribute

```

(* no_rw_check *)
reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];

always @(posedge clk) begin
    if (write_enable)

```

(continues on next page)

(continued from previous page)

```

        mem[write_addr] <= write_data;

    if (read_enable)
        read_data <= mem[read_addr];
end

```

10.2.5 Synchronous SDP with write-first behavior

- Will result in block RAM or LUT RAM depending on size
- May use additional circuitry for block RAM if write-first is not natively supported. Will always use additional circuitry for LUT RAM.

```

reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];

always @(posedge clk) begin
    if (write_enable)
        mem[write_addr] <= write_data;

    if (read_enable) begin
        read_data <= mem[read_addr];
        if (write_enable && read_addr == write_addr)
            read_data <= write_data;
    end
end

```

10.2.6 Synchronous SDP with write-first behavior (alternate pattern)

- This pattern is supported for compatibility, but is much less flexible than the above

```

reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];

always @(posedge clk) begin
    if (write_enable)
        mem[write_addr] <= write_data;
    read_addr_reg <= read_addr;
end

assign read_data = mem[read_addr_reg];

```

10.3 Single-port RAM memory patterns

10.3.1 Asynchronous-read single-port RAM

- Will result in single-port LUT RAM on supported targets

```
reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];
always @(posedge clk)
    if (write_enable)
        mem[addr] <= write_data;
assign read_data = mem[addr];
```

10.3.2 Synchronous single-port RAM with mutually exclusive read/write

- Will result in single-port block RAM or LUT RAM depending on size
- This is the correct pattern to infer ice40 SPRAM (with manual ram_style selection)
- On targets that don't support read/write block RAM ports (eg. ice40), will result in SDP block RAM instead
- For block RAM, will use "NO_CHANGE" mode if available

```
reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];

always @(posedge clk) begin
    if (write_enable)
        mem[addr] <= write_data;
    else if (read_enable)
        read_data <= mem[addr];
end
```

10.3.3 Synchronous single-port RAM with read-first behavior

- Will only result in single-port block RAM when read-first behavior is natively supported; otherwise, SDP RAM with additional circuitry will be used
- Many targets (Xilinx, ECP5, ...) can only natively support read-first/write-first single-port RAM (or TDP RAM) where the write_enable signal implies the read_enable signal (ie. can never write without reading). The memory inference code will run a simple SAT solver on the control signals to determine if this is the case, and insert emulation circuitry if it cannot be easily proven.

```
reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];

always @(posedge clk) begin
    if (write_enable)
        mem[addr] <= write_data;
    if (read_enable)
        read_data <= mem[addr];
end
```

10.3.4 Synchronous single-port RAM with write-first behavior

- Will result in single-port block RAM or LUT RAM when supported
- Block RAMs will require extra circuitry if write-first behavior not natively supported

```
reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];

always @(posedge clk) begin
    if (write_enable)
        mem[addr] <= write_data;
    if (read_enable)
        if (write_enable)
            read_data <= write_data;
        else
            read_data <= mem[addr];
end
```

10.3.5 Synchronous read port with initial value

- Initial read port values can be combined with any other supported pattern
- If block RAM is used and initial read port values are not natively supported by the target, small emulation circuit will be inserted

```
reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];
reg [DATA_WIDTH - 1 : 0] read_data;
initial read_data = 'h1234;

always @(posedge clk) begin
    if (write_enable)
        mem[write_addr] <= write_data;
    if (read_enable)
        read_data <= mem[read_addr];
end
```

10.4 Read register reset patterns

Resets can be combined with any other supported pattern (except that synchronous reset and asynchronous reset cannot both be used on a single read port). If block RAM is used and the selected reset (synchronous or asynchronous) is used but not natively supported by the target, small emulation circuitry will be inserted.

10.4.1 Synchronous reset, reset priority over enable

```
reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];

always @(posedge clk) begin
    if (write_enable)
        mem[write_addr] <= write_data;

    if (read_reset)
        read_data <= {sval};
    else if (read_enable)
        read_data <= mem[read_addr];
end
```

10.4.2 Synchronous reset, enable priority over reset

```
reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];

always @(posedge clk) begin
    if (write_enable)
        mem[write_addr] <= write_data;
    if (read_enable)
        if (read_reset)
            read_data <= 'h1234;
        else
            read_data <= mem[read_addr];
end
```

10.4.3 Synchronous read port with asynchronous reset

```
reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];

always @(posedge clk) begin
    if (write_enable)
        mem[write_addr] <= write_data;
end

always @(posedge clk, posedge reset_read) begin
    if (reset_read)
        read_data <= 'h1234;
    else if (read_enable)
```

(continues on next page)

(continued from previous page)

```

        read_data <= mem[read_addr];
end

```

10.5 Asymmetric memory patterns

To construct an asymmetric memory (memory with read/write ports of differing widths):

- Declare the memory with the width of the narrowest intended port
- Split all wide ports into multiple narrow ports
- To ensure the wide ports will be correctly merged:
 - For the address, use a concatenation of actual address in the high bits and a constant in the low bits
 - Ensure the actual address is identical for all ports belonging to the wide port
 - Ensure that clock is identical
 - For read ports, ensure that enable/reset signals are identical (for write ports, the enable signal may vary — this will result in using the byte enable functionality)

Asymmetric memory is supported on all targets, but may require emulation circuitry where not natively supported. Note that when the memory is larger than the underlying block RAM primitive, hardware asymmetric memory support is likely not to be used even if present as it is more expensive.

10.5.1 Wide synchronous read port

```

reg [7:0] mem [0:255];
wire [7:0] write_addr;
wire [5:0] read_addr;
wire [7:0] write_data;
reg [31:0] read_data;

always @(posedge clk) begin
    if (write_enable)
        mem[write_addr] <= write_data;
    if (read_enable) begin
        read_data[7:0] <= mem[{read_addr, 2'b00}];
        read_data[15:8] <= mem[{read_addr, 2'b01}];
        read_data[23:16] <= mem[{read_addr, 2'b10}];
        read_data[31:24] <= mem[{read_addr, 2'b11}];
    end
end
end

```

10.5.2 Wide asynchronous read port

- Note: the only target natively supporting this pattern is Xilinx UltraScale

```
reg [7:0] mem [0:511];
wire [8:0] write_addr;
wire [5:0] read_addr;
wire [7:0] write_data;
wire [63:0] read_data;

always @(posedge clk) begin
    if (write_enable)
        mem[write_addr] <= write_data;
end

assign read_data[7:0] = mem[{read_addr, 3'b000}];
assign read_data[15:8] = mem[{read_addr, 3'b001}];
assign read_data[23:16] = mem[{read_addr, 3'b010}];
assign read_data[31:24] = mem[{read_addr, 3'b011}];
assign read_data[39:32] = mem[{read_addr, 3'b100}];
assign read_data[47:40] = mem[{read_addr, 3'b101}];
assign read_data[55:48] = mem[{read_addr, 3'b110}];
assign read_data[63:56] = mem[{read_addr, 3'b111}];
```

10.5.3 Wide write port

```
reg [7:0] mem [0:255];
wire [5:0] write_addr;
wire [7:0] read_addr;
wire [31:0] write_data;
reg [7:0] read_data;

always @(posedge clk) begin
    if (write_enable[0])
        mem[{write_addr, 2'b00}] <= write_data[7:0];
    if (write_enable[1])
        mem[{write_addr, 2'b01}] <= write_data[15:8];
    if (write_enable[2])
        mem[{write_addr, 2'b10}] <= write_data[23:16];
    if (write_enable[3])
        mem[{write_addr, 2'b11}] <= write_data[31:24];
    if (read_enable)
        read_data <= mem[read_addr];
end
```

10.6 True dual port (TDP) patterns

- Many different variations of true dual port memory can be created by combining two single-port RAM patterns on the same memory
- When TDP memory is used, memory inference code has much less maneuver room to create requested semantics compared to individual single-port patterns (which can end up lowered to SDP memory where necessary) — supported patterns depend strongly on the target
- In particular, when both ports have the same clock, it's likely that “undefined collision” mode needs to be manually selected to enable TDP memory inference
- The examples below are non-exhaustive — many more combinations of port types are possible
- Note: if two write ports are in the same process, this defines a priority relation between them (if both ports are active in the same clock, the later one wins). On almost all targets, this will result in a bit of extra circuitry to ensure the priority semantics. If this is not what you want, put them in separate processes.
 - Priority is not supported when using the verilog front end and any priority semantics are ignored.

10.6.1 TDP with different clocks, exclusive read/write

```
reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];

always @(posedge clk_a) begin
    if (write_enable_a)
        mem[addr_a] <= write_data_a;
    else if (read_enable_a)
        read_data_a <= mem[addr_a];
end

always @(posedge clk_b) begin
    if (write_enable_b)
        mem[addr_b] <= write_data_b;
    else if (read_enable_b)
        read_data_b <= mem[addr_b];
end
```

10.6.2 TDP with same clock, read-first behavior

- This requires hardware inter-port read-first behavior, and will only work on some targets (Xilinx, Nexus)

```
reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];

always @(posedge clk) begin
    if (write_enable_a)
        mem[addr_a] <= write_data_a;
    if (read_enable_a)
        read_data_a <= mem[addr_a];
end
```

(continues on next page)

(continued from previous page)

```

always @(posedge clk) begin
    if (write_enable_b)
        mem[addr_b] <= write_data_b;
    if (read_enable_b)
        read_data_b <= mem[addr_b];
end

```

10.6.3 TDP with multiple read ports

- The combination of a single write port with an arbitrary amount of read ports is supported on all targets — if a multi-read port primitive is available (like Xilinx RAM64M), it'll be used as appropriate. Otherwise, the memory will be automatically split into multiple primitives.

```

reg [31:0] mem [0:31];

always @(posedge clk) begin
    if (write_enable)
        mem[write_addr] <= write_data;
end

assign read_data_a = mem[read_addr_a];
assign read_data_b = mem[read_addr_b];
assign read_data_c = mem[read_addr_c];

```

10.7 Not yet supported patterns

10.7.1 Synchronous SDP with write-first behavior via blocking assignments

- Would require modifications to the Yosys Verilog frontend.
- Use *Synchronous SDP with write-first behavior* instead

```

reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];

always @(posedge clk) begin
    if (write_enable)
        mem[write_addr] = write_data;

    if (read_enable)
        read_data <= mem[read_addr];
end

```

10.7.2 Asymmetric memories via part selection

- Would require major changes to the Verilog frontend.
- Build wide ports out of narrow ports instead (see *Wide synchronous read port*)

```
reg [31:0] mem [2**ADDR_WIDTH - 1 : 0];

wire [1:0] byte_lane;
wire [7:0] write_data;

always @(posedge clk) begin
    if (write_enable)
        mem[write_addr][byte_lane * 8 +: 8] <= write_data;

    if (read_enable)
        read_data <= mem[read_addr];
end
```

10.8 Undesired patterns

10.8.1 Asynchronous writes

- Not supported in modern FPGAs
- Not supported in yosys code anyhow

```
reg [DATA_WIDTH - 1 : 0] mem [2**ADDR_WIDTH - 1 : 0];

always @* begin
    if (write_enable)
        mem[write_addr] = write_data;
end

assign read_data = mem[read_addr];
```

AUXILIARY LIBRARIES

The Yosys source distribution contains some auxiliary libraries that are bundled with Yosys.

A.1 SHA1

The files in `libs/sha1/` provide a public domain SHA1 implementation written by Steve Reid, Bruce Guenter, and Volker Grabsch. It is used for generating unique names when specializing parameterized modules.

A.2 BigInt

The files in `libs/bigint/` provide a library for performing arithmetic with arbitrary length integers. It is written by Matt McCutchen.

The BigInt library is used for evaluating constant expressions, e.g. using the `ConstEval` class provided in `kernel/consteval.h`.

See also: <http://mattmccutchen.net/bigint/>

A.3 SubCircuit

The files in `libs/subcircuit` provide a library for solving the subcircuit isomorphism problem. It is written by C. Wolf and based on the Ullmann Subgraph Isomorphism Algorithm [Ull76]. It is used by the `extract` pass (see *extract - find subcircuits and replace them with cells*).

A.4 ezSAT

The files in `libs/ezsat` provide a library for simplifying generating CNF formulas for SAT solvers. It also contains bindings of MiniSAT. The ezSAT library is written by C. Wolf. It is used by the `sat` pass (see *sat - solve a SAT problem in the circuit*).

AUXILIARY PROGRAMS

Besides the main yosys executable, the Yosys distribution contains a set of additional helper programs.

B.1 yosys-config

The yosys-config tool (an auto-generated shell-script) can be used to query compiler options and other information needed for building loadable modules for Yosys. See Sec. [Section 6](#) for details.

B.2 yosys-filterlib

The yosys-filterlib tool is a small utility that can be used to strip or extract information from a Liberty file. See [Sec. 9.3](#) for details.

B.3 yosys-abc

This is a fork of ABC with a small set of custom modifications that have not yet been accepted upstream. Not all versions of Yosys work with all versions of ABC. So Yosys comes with its own yosys-abc to avoid compatibility issues between the two.

RTLIL TEXT REPRESENTATION

This appendix documents the text representation of RTLIL in extended Backus-Naur form (EBNF).

The grammar is not meant to represent semantic limitations. That is, the grammar is “permissive”, and later stages of processing perform more rigorous checks.

The grammar is also not meant to represent the exact grammar used in the RTLIL frontend, since that grammar is specific to processing by lex and yacc, is even more permissive, and is somewhat less understandable than simple EBNF notation.

Finally, note that all statements (rules ending in `-stmt`) terminate in an end-of-line. Because of this, a statement cannot be broken into multiple lines.

C.1 Lexical elements

C.1.1 Characters

An RTLIL file is a stream of bytes. Strictly speaking, a “character” in an RTLIL file is a single byte. The lexer treats multi-byte encoded characters as consecutive single-byte characters. While other encodings *may* work, UTF-8 is known to be safe to use. Byte order marks at the beginning of the file will cause an error.

ASCII spaces (32) and tabs (9) separate lexer tokens.

A `nonws` character, used in identifiers, is any character whose encoding consists solely of bytes above ASCII space (32).

An `eof` is one or more consecutive ASCII newlines (10) and carriage returns (13).

C.1.2 Identifiers

There are two types of identifiers in RTLIL:

- Publically visible identifiers
- Auto-generated identifiers

```
<id> ::= <public-id> | <autogen-id>
<public-id> ::= \ <nonws>+
<autogen-id> ::= $ <nonws>+
```

C.1.3 Values

A *value* consists of a width in bits and a bit representation, most significant bit first. Bits may be any of:

- 0: A logic zero value
- 1: A logic one value
- x: An unknown logic value (or don't care in case patterns)
- z: A high-impedance value (or don't care in case patterns)
- m: A marked bit (internal use only)
- -: A don't care value

An *integer* is simply a signed integer value in decimal format. **Warning:** Integer constants are limited to 32 bits. That is, they may only be in the range $[-2147483648, 2147483648]$. Integers outside this range will result in an error.

```
<value>      ::= <decimal-digit>+ ' ' <binary-digit>*  
<decimal-digit> ::= 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9  
<binary-digit> ::= 0 | 1 | x | z | m | -  
<integer>    ::= -? <decimal-digit>+
```

C.1.4 Strings

A string is a series of characters delimited by double-quote characters. Within a string, any character except ASCII NUL (0) may be used. In addition, certain escapes can be used:

- \n: A newline
- \t: A tab
- \ooo: A character specified as a one, two, or three digit octal value

All other characters may be escaped by a backslash, and become the following character. Thus:

- \\: A backslash
- \": A double-quote
- \r: An 'r' character

C.1.5 Comments

A comment starts with a # character and proceeds to the end of the line. All comments are ignored.

C.2 File

A file consists of an optional autoindex statement followed by zero or more modules.

```
<file> ::= <autoidx-stmt>? <module>*
```

C.2.1 Autoindex statements

The autoindex statement sets the global autoindex value used by Yosys when it needs to generate a unique name, e.g. `flattenN`. The N part is filled with the value of the global autoindex value, which is subsequently incremented. This global has to be dumped into RTLIL, otherwise e.g. dumping and running a pass would have different properties than just running a pass on a warm design.

```
<autoidx-stmt> ::= autoidx <integer> <eol>
```

C.2.2 Modules

Declares a module, with zero or more attributes, consisting of zero or more wires, memories, cells, processes, and connections.

```
<module>          ::= <attr-stmt>* <module-stmt> <module-body> <module-end-stmt>
<module-stmt>     ::= module <id> <eol>
<module-body>     ::= (<param-stmt>
                        | <wire>
                        | <memory>
                        | <cell>
                        | <process>)*
<param-stmt>      ::= parameter <id> <constant>? <eol>
<constant>        ::= <value> | <integer> | <string>
<module-end-stmt> ::= end <eol>
```

C.2.3 Attribute statements

Declares an attribute with the given identifier and value.

```
<attr-stmt> ::= attribute <id> <constant> <eol>
```

C.2.4 Signal specifications

A signal is anything that can be applied to a cell port, i.e. a constant value, all bits or a selection of bits from a wire, or concatenations of those.

Warning: When an integer constant is a sigspec, it is always 32 bits wide, 2's complement. For example, a constant of `-1` is the same as `32'11111111111111111111111111111111`, while a constant of `1` is the same as `32'1`.

See [Sec. 4.2.4](#) for an overview of signal specifications.

```
<sigspec> ::= <constant>
           | <wire-id>
           | <sigspec> [ <integer> (:<integer>)? ]
           | { <sigspec>* }
```

C.2.5 Connections

Declares a connection between the given signals.

```
<conn-stmt> ::= connect <sigspec> <sigspec> <eol>
```

C.2.6 Wires

Declares a wire, with zero or more attributes, with the given identifier and options in the enclosing module.

See [Sec. 4.2.3](#) for an overview of wires.

```
<wire>          ::= <attr-stmt>* <wire-stmt>
<wire-stmt>     ::= wire <wire-option>* <wire-id> <eol>
<wire-id>       ::= <id>
<wire-option>   ::= width <integer>
                  | offset <integer>
                  | input <integer>
                  | output <integer>
                  | inout <integer>
                  | upto
                  | signed
```

C.2.7 Memories

Declares a memory, with zero or more attributes, with the given identifier and options in the enclosing module.

See [Sec. 4.2.6](#) for an overview of memory cells, and [Sec. 5.1.5](#) for details about memory cell types.

```
<memory>        ::= <attr-stmt>* <memory-stmt>
<memory-stmt>   ::= memory <memory-option>* <id> <eol>
<memory-option> ::= width <integer>
                  | size <integer>
                  | offset <integer>
```

C.2.8 Cells

Declares a cell, with zero or more attributes, with the given identifier and type in the enclosing module.

Cells perform functions on input signals. See [Chap. 5](#) for a detailed list of cell types.

```
<cell>          ::= <attr-stmt>* <cell-stmt> <cell-body-stmt>* <cell-end-stmt>
<cell-stmt>     ::= cell <cell-type> <cell-id> <eol>
<cell-id>       ::= <id>
<cell-type>     ::= <id>
<cell-body-stmt> ::= parameter (signed | real)? <id> <constant> <eol>
                  | connect <id> <sigspec> <eol>
<cell-end-stmt> ::= end <eol>
```

C.2.9 Processes

Declares a process, with zero or more attributes, with the given identifier in the enclosing module. The body of a process consists of zero or more assignments, exactly one switch, and zero or more syncs.

See Sec. 4.2.5 for an overview of processes.

```
<process>      ::= <attr-stmt>* <proc-stmt> <process-body> <proc-end-stmt>
<proc-stmt>    ::= process <id> <eol>
<process-body> ::= <assign-stmt>* <switch>? <assign-stmt>* <sync>*
<assign-stmt>  ::= assign <dest-sigspec> <src-sigspec> <eol>
<dest-sigspec> ::= <sigspec>
<src-sigspec>  ::= <sigspec>
<proc-end-stmt> ::= end <eol>
```

C.2.10 Switches

Switches test a signal for equality against a list of cases. Each case specifies a comma-separated list of signals to check against. If there are no signals in the list, then the case is the default case. The body of a case consists of zero or more switches and assignments. Both switches and cases may have zero or more attributes.

```
<switch>      ::= <switch-stmt> <case>* <switch-end-stmt>
<switch-stmt> ::= <attr-stmt>* switch <sigspec> <eol>
<case>        ::= <attr-stmt>* <case-stmt> <case-body>
<case-stmt>   ::= case <compare>? <eol>
<compare>     ::= <sigspec> (, <sigspec>)*
<case-body>   ::= (<switch> | <assign-stmt>)*
<switch-end-stmt> ::= end <eol>
```

C.2.11 Syncs

Syncs update signals with other signals when an event happens. Such an event may be:

- An edge or level on a signal
- Global clock ticks
- Initialization
- Always

```
<sync>        ::= <sync-stmt> <update-stmt>*
<sync-stmt>   ::= sync <sync-type> <sigspec> <eol>
               | sync global <eol>
               | sync init <eol>
               | sync always <eol>
<sync-type>   ::= low | high | posedge | negedge | edge
<update-stmt> ::= update <dest-sigspec> <src-sigspec> <eol>
```

010: CONVERTING VERILOG TO BLIF PAGE

D.1 Installation

Yosys written in C++ (using features from C++11) and is tested on modern Linux. It should compile fine on most UNIX systems with a C++11 compiler. The README file contains useful information on building Yosys and its prerequisites.

Yosys is a large and feature-rich program with a couple of dependencies. It is, however, possible to deactivate some of the dependencies in the Makefile, resulting in features in Yosys becoming unavailable. When problems with building Yosys are encountered, a user who is only interested in the features of Yosys that are discussed in this Application Note may deactivate TCL, Qt and MiniSAT support in the Makefile and may opt against building yosys-abc.

This Application Note is based on [Yosys GIT Rev. e216e0e](#) from 2013-11-23. The Verilog sources used for the examples are taken from [yosys-bigsim](#), a collection of real-world designs used for regression testing Yosys.

D.2 Getting started

We start our tour with the Navré processor from yosys-bigsim. The [Navré processor](#) is an Open Source AVR clone. It is a single module (softusb_navre) in a single design file (softusb_navre.v). It also is using only features that map nicely to the BLIF format, for example it only uses synchronous resets.

Converting softusb_navre.v to softusb_navre.blif could not be easier:

```
yosys -o softusb_navre.blif -S softusb_navre.v
```

Behind the scenes Yosys is controlled by synthesis scripts that execute commands that operate on Yosys' internal state. For example, the `-o softusb_navre.blif` option just adds the command `write_blif softusb_navre.blif` to the end of the script. Likewise a file on the command line – `softusb_navre.v` in this case – adds the command `read_verilog softusb_navre.v` to the beginning of the synthesis script. In both cases the file type is detected from the file extension.

Finally the option `-S` instantiates a built-in default synthesis script. Instead of using `-S` one could also specify the synthesis commands for the script on the command line using the `-p` option, either using individual options for each command or by passing one big command string with a semicolon-separated list of commands. But in most cases it is more convenient to use an actual script file.

D.3 Using a synthesis script

With a script file we have better control over Yosys. The following script file replicates what the command from the last section did:

```
read_verilog softusb_navre.v
hierarchy
proc; opt; memory; opt; techmap; opt
write_blif softusb_navre.blif
```

The first and last line obviously read the Verilog file and write the BLIF file.

The 2nd line checks the design hierarchy and instantiates parametrized versions of the modules in the design, if necessary. In the case of this simple design this is a no-op. However, as a general rule a synthesis script should always contain this command as first command after reading the input files.

The 3rd line does most of the actual work:

- The command `opt` is the Yosys' built-in optimizer. It can perform some simple optimizations such as const-folding and removing unconnected parts of the design. It is common practice to call `opt` after each major step in the synthesis procedure. In cases where too much optimization is not appreciated (for example when analyzing a design), it is recommended to call `clean` instead of `opt`.
- The command `proc` converts processes (Yosys' internal representation of Verilog always- and initial-blocks) to circuits of multiplexers and storage elements (various types of flip-flops).
- The command `memory` converts Yosys' internal representations of arrays and array accesses to multi-port block memories, and then maps this block memories to address decoders and flip-flops, unless the option `-nomap` is used, in which case the multi-port block memories stay in the design and can then be mapped to architecture-specific memory primitives using other commands.
- The command `techmap` turns a high-level circuit with coarse grain cells such as wide adders and multipliers to a fine-grain circuit of simple logic primitives and single-bit storage elements. The command does that by substituting the complex cells by circuits of simpler cells. It is possible to provide a custom set of rules for this process in the form of a Verilog source file, as we will see in the next section.

Now Yosys can be run with the filename of the synthesis script as argument:

```
yosys softusb_navre.js
```

Now that we are using a synthesis script we can easily modify how Yosys synthesizes the design. The first thing we should customize is the call to the `hierarchy` command:

Whenever it is known that there are no implicit blackboxes in the design, i.e. modules that are referenced but are not defined, the `hierarchy` command should be called with the `-check` option. This will then cause synthesis to fail when implicit blackboxes are found in the design.

The 2nd thing we can improve regarding the `hierarchy` command is that we can tell it the name of the top level module of the design hierarchy. It will then automatically remove all modules that are not referenced from this top level module.

For many designs it is also desired to optimize the encodings for the finite state machines (FSMs) in the design. The `fsm` command finds FSMs, extracts them, performs some basic optimizations and then generate a circuit from the extracted and optimized description. It would also be possible to tell the `fsm` command to leave the FSMs in their extracted form, so they can be further processed using custom commands. But in this case we don't want that.

So now we have the final synthesis script for generating a BLIF file for the Navré CPU:

```

read_verilog softusb_navre.v
hierarchy -check -top softusb_navre
proc; opt; memory; opt; fsm; opt; techmap; opt
write_blif softusb_navre.blif

```

D.4 Advanced example: The Amber23 ARMv2a CPU

Our 2nd example is the [Amber23 ARMv2a CPU](#). Once again we base our example on the Verilog code that is included in `yosys-bigsim`.

Listing 4.1: *amber23.ys*

```

read_verilog a23_alu.v
read_verilog a23_barrel_shift_fpga.v
read_verilog a23_barrel_shift.v
read_verilog a23_cache.v
read_verilog a23_coprocessor.v
read_verilog a23_core.v
read_verilog a23_decode.v
read_verilog a23_execute.v
read_verilog a23_fetch.v
read_verilog a23_multiply.v
read_verilog a23_ram_register_bank.v
read_verilog a23_register_bank.v
read_verilog a23_wishbone.v
read_verilog generic_sram_byte_en.v
read_verilog generic_sram_line_en.v
hierarchy -check -top a23_core
add -global_input globrst 1
proc -global_arst globrst
techmap -map adff2dff.v
opt; memory; opt; fsm; opt; techmap
write_blif amber23.blif

```

The problem with this core is that it contains no dedicated reset logic. Instead the coding techniques shown in [Listing 4.2](#) are used to define reset values for the global asynchronous reset in an FPGA implementation. This design can not be expressed in BLIF as it is. Instead we need to use a synthesis script that transforms this form to synchronous resets that can be expressed in BLIF.

(Note that there is no problem if this coding techniques are used to model ROM, where the register is initialized using this syntax but is never updated otherwise.)

[Listing 4.1](#) shows the synthesis script for the Amber23 core. In line 17 the `add` command is used to add a 1-bit wide global input signal with the name `globrst`. That means that an input with that name is added to each module in the design hierarchy and then all module instantiations are altered so that this new signal is connected throughout the whole design hierarchy.

Listing 4.2: Implicit coding of global asynchronous resets

```

reg [7:0] a = 13, b;
initial b = 37;

```

Listing 4.3: *adff2dff.v*

```

(* techmap_celltype = "$adff" *)
module adff2dff (CLK, ARST, D, Q);

parameter WIDTH = 1;
parameter CLK_POLARITY = 1;
parameter ARST_POLARITY = 1;
parameter ARST_VALUE = 0;

input CLK, ARST;
input [WIDTH-1:0] D;
output reg [WIDTH-1:0] Q;

wire [1023:0] _TECHMAP_DO_ = "proc";

wire _TECHMAP_FAIL_ =
    !CLK_POLARITY || !ARST_POLARITY;

always @(posedge CLK)
    if (ARST)
        Q <= ARST_VALUE;
    else
        Q <= D;

endmodule

```

In line 18 the proc command is called. But in this script the signal name `globrst` is passed to the command as a global reset signal for resetting the registers to their assigned initial values.

Finally in line 19 the techmap command is used to replace all instances of flip-flops with asynchronous resets with flip-flops with synchronous resets. The map file used for this is shown in [Listing 4.3](#). Note how the `techmap_celltype` attribute is used in line 1 to tell the techmap command which cells to replace in the design, how the `_TECHMAP_FAIL_` wire in lines 15 and 16 (which evaluates to a constant value) determines if the parameter set is compatible with this replacement circuit, and how the `_TECHMAP_DO_` wire in line 13 provides a mini synthesis-script to be used to process this cell.

Listing 4.4: Test program for the Amber23 CPU (Sieve of Eratosthenes). Compiled using GCC 4.6.3 for ARM with `-Os -marm -march=armv2a -mno-thumb-interwork -ffreestanding`, linked with `--fix-v4bx` set and booted with a custom setup routine written in ARM assembler.

```

#include <stdint.h>
#include <stdbool.h>

#define BITMAP_SIZE 64
#define OUTPUT 0x10000000

static uint32_t bitmap[BITMAP_SIZE/32];

static void bitmap_set(uint32_t idx) { bitmap[idx/32] |= 1 << (idx % 32); }
static bool bitmap_get(uint32_t idx) { return (bitmap[idx/32] & (1 << (idx % 32))) != 0; }

```

(continues on next page)

(continued from previous page)

```

↪}
static void output(uint32_t val) { *((volatile uint32_t*)OUTPORT) = val; }

int main() {
    uint32_t i, j, k;
    output(2);
    for (i = 0; i < BITMAP_SIZE; i++) {
        if (bitmap_get(i)) continue;
        output(3+2*i);
        for (j = 2*(3+2*i); j += 3+2*i) {
            if (j%2 == 0) continue;
            k = (j-3)/2;
            if (k >= BITMAP_SIZE) break;
            bitmap_set(k);
        }
    }
    output(0);
    return 0;
}

```

D.5 Verification of the Amber23 CPU

The BLIF file for the Amber23 core, generated using [Listing 4.1](#) and [Listing 4.3](#) and the version of the Amber23 RTL source that is bundled with yosys-bigsim, was verified using the test-bench from yosys-bigsim. It successfully executed the program shown in [Listing 4.4](#) in the test-bench.

For simulation the BLIF file was converted back to Verilog using [ABC](#). So this test includes the successful transformation of the BLIF file into ABC's internal format as well.

The only thing left to write about the simulation itself is that it probably was one of the most energy inefficient and time consuming ways of successfully calculating the first 31 primes the author has ever conducted.

D.6 Limitations

At the time of this writing Yosys does not support multi-dimensional memories, does not support writing to individual bits of array elements, does not support initialization of arrays with \$readmemb and \$readmemh, and has only limited support for tristate logic, to name just a few limitations.

That being said, Yosys can synthesize an overwhelming majority of real-world Verilog RTL code. The remaining cases can usually be modified to be compatible with Yosys quite easily.

The various designs in yosys-bigsim are a good place to look for examples of what is within the capabilities of Yosys.

D.7 Conclusion

Yosys is a feature-rich Verilog-2005 synthesis tool. It has many uses, but one is to provide an easy gateway from high-level Verilog code to low-level logic circuits.

The command line option `-S` can be used to quickly synthesize Verilog code to BLIF files without a hassle.

With custom synthesis scripts it becomes possible to easily perform high-level optimizations, such as re-encoding FSMs. In some extreme cases, such as the Amber23 ARMv2 CPU, the more advanced Yosys features can be used to change a design to fit a certain need without actually touching the RTL code.

011: INTERACTIVE DESIGN INVESTIGATION PAGE

E.1 Installation and prerequisites

This Application Note is based on the [Yosys GIT Rev. 2b90ba1](#) from 2013-12-08. The README file covers how to install Yosys. The `show` command requires a working installation of [GraphViz](#) and `xdot` for generating the actual circuit diagrams.

E.2 Overview

This application note is structured as follows:

Introduction to the show command introduces the `show` command and explains the symbols used in the circuit diagrams generated by it.

Navigating the design introduces additional commands used to navigate in the design, select portions of the design, and print additional information on the elements in the design that are not contained in the circuit diagrams.

Advanced investigation techniques introduces commands to evaluate the design and solve SAT problems within the design.

Conclusion concludes the document and summarizes the key points.

E.3 Introduction to the show command

Listing 5.1: Yosys script with `show` commands and example design

```
$ cat example.js
read_verilog example.v
show -pause
proc
show -pause
opt
show -pause

$ cat example.v
module example(input clk, a, b, c,
               output reg [1:0] y);
    always @(posedge clk)
```

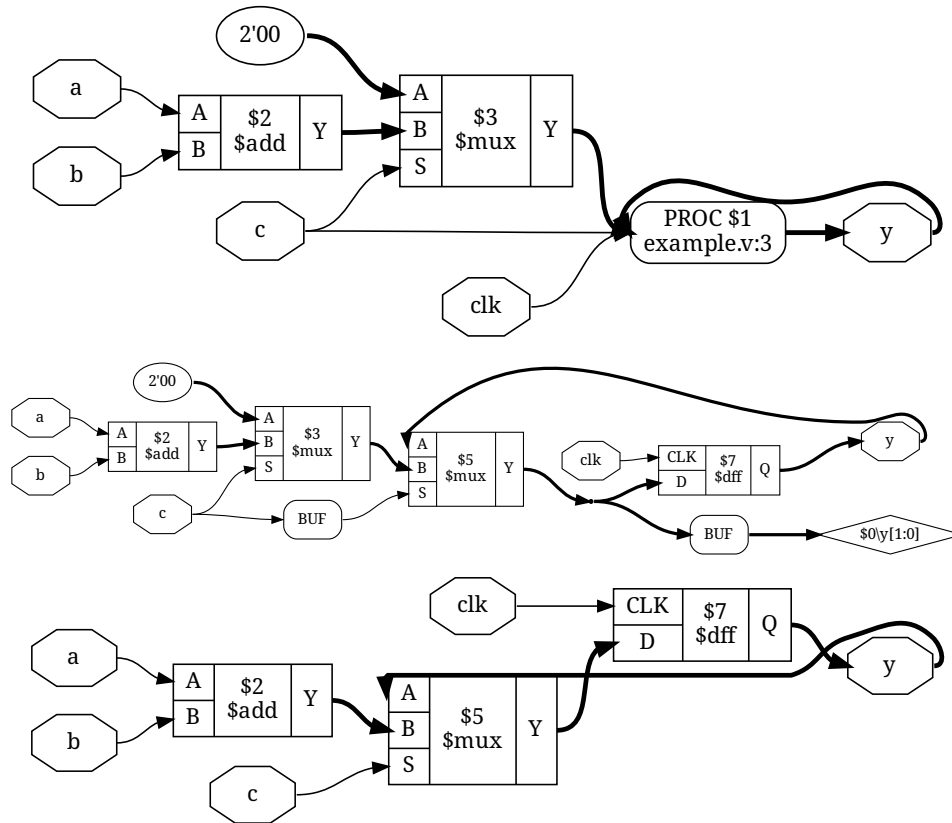

(continues on next page)

(continued from previous page)

```

    if (c)
        y <= c ? a + b : 2'd0;
endmodule

```

Fig. 5.1: Output of the three `show` commands from Listing 5.1

The `show` command generates a circuit diagram for the design in its current state. Various options can be used to change the appearance of the circuit diagram, set the name and format for the output file, and so forth. When called without any special options, it saves the circuit diagram in a temporary file and launches `xdot` to display the diagram. Subsequent calls to `show` re-use the `xdot` instance (if still running).

E.3.1 A simple circuit

Listing 5.1 shows a simple synthesis script and a Verilog file that demonstrate the usage of `show` in a simple setting. Note that `show` is called with the `-pause` option, that halts execution of the Yosys script until the user presses the Enter key. The `show -pause` command also allows the user to enter an interactive shell to further investigate the circuit before continuing synthesis.

So this script, when executed, will show the design after each of the three synthesis commands. The generated circuit diagrams are shown in Fig. 5.1.

The first diagram (from top to bottom) shows the design directly after being read by the Verilog front-end.

Input and output ports are displayed as octagonal shapes. Cells are displayed as rectangles with inputs on the left and outputs on the right side. The cell labels are two lines long: The first line contains a unique identifier for the cell and the second line contains the cell type. Internal cell types are prefixed with a dollar sign. The Yosys manual contains a chapter on the internal cell library used in Yosys.

Constants are shown as ellipses with the constant value as label. The syntax `<bit_width>'<bits>` is used for constants that are not 32-bit wide and/or contain bits that are not 0 or 1 (i.e. `x` or `z`). Ordinary 32-bit constants are written using decimal numbers.

Single-bit signals are shown as thin arrows pointing from the driver to the load. Signals that are multiple bits wide are shown as thick arrows.

Finally *processes* are shown in boxes with round corners. Processes are Yosys' internal representation of the decision-trees and synchronization events modelled in a Verilog `always`-block. The label reads `PROC` followed by a unique identifier in the first line and contains the source code location of the original `always`-block in the 2nd line. Note how the multiplexer from the `?:`-expression is represented as a `$mux` cell but the multiplexer from the `if`-statement is yet still hidden within the process.

The `proc` command transforms the process from the first diagram into a multiplexer and a d-type flip-flop, which brings us to the 2nd diagram.

The Rhombus shape to the right is a dangling wire. (Wire nodes are only shown if they are dangling or have “public” names, for example names assigned from the Verilog input.) Also note that the design now contains two instances of a `BUF`-node. These are artefacts left behind by the `proc`-command. It is quite usual to see such artefacts after calling commands that perform changes in the design, as most commands only care about doing the transformation in the least complicated way, not about cleaning up after them. The next call to `clean` (or `opt`, which includes `clean` as one of its operations) will clean up these artefacts. This operation is so common in Yosys scripts that it can simply be abbreviated with the `;;` token, which doubles as separator for commands. Unless one wants to specifically analyze these artefacts left behind some operations, it is therefore recommended to always call `clean` before calling `show`.

In this script we directly call `opt` as next step, which finally leads us to the 3rd diagram in [Fig. 5.1](#). Here we see that the `opt` command not only has removed the artifacts left behind by `proc`, but also determined correctly that it can remove the first `$mux` cell without changing the behavior of the circuit.

Fig. 5.2: Output of `yosys -p 'proc; opt; show' splice.v`

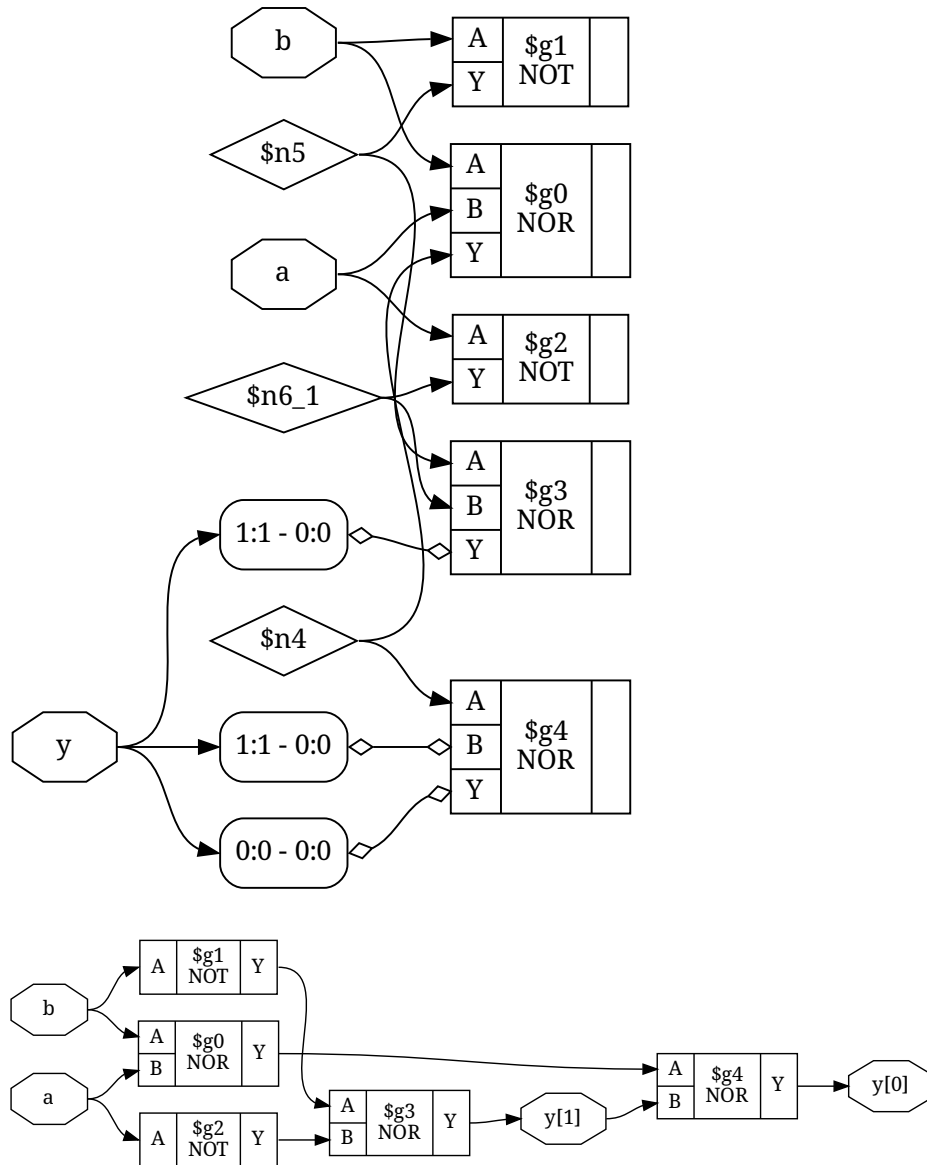

Fig. 5.3: Effects of `splitnets` command and of providing a cell library. (The circuit is a half-adder built from simple CMOS gates.)

Listing 5.2: splice.v

```

module splice_demo(a, b, c, d, e, f, x, y);

input [1:0] a, b, c, d, e, f;
output [1:0] x = {a[0], a[1]};

output [11:0] y;
assign {y[11:4], y[1:0], y[3:2]} =
        {a, b, ~{c, d}, ~{e, f}};

endmodule

```

E.3.2 Break-out boxes for signal vectors

As has been indicated by the last example, Yosys is can manage signal vectors (aka. multi-bit wires or buses) as native objects. This provides great advantages when analyzing circuits that operate on wide integers. But it also introduces some additional complexity when the individual bits of of a signal vector are accessed. The example **show** in [Listing 5.2](#) demonstrates how such circuits are visualized by the **show** command.

The key elements in understanding this circuit diagram are of course the boxes with round corners and rows labeled `<MSB_LEFT>:<LSB_LEFT>` - `<MSB_RIGHT>:<LSB_RIGHT>`. Each of this boxes has one signal per row on one side and a common signal for all rows on the other side. The `<MSB>:<LSB>` tuples specify which bits of the signals are broken out and connected. So the top row of the box connecting the signals **a** and **x** indicates that the bit 0 (i.e. the range 0:0) from signal **a** is connected to bit 1 (i.e. the range 1:1) of signal **x**.

Lines connecting such boxes together and lines connecting such boxes to cell ports have a slightly different look to emphasise that they are not actual signal wires but a necessity of the graphical representation. This distinction seems like a technicality, until one wants to debug a problem related to the way Yosys internally represents signal vectors, for example when writing custom Yosys commands.

E.3.3 Gate level netlists

Finally [Fig. 5.3](#) shows two common pitfalls when working with designs mapped to a cell library. The top figure has two problems: First Yosys did not have access to the cell library when this diagram was generated, resulting in all cell ports defaulting to being inputs. This is why all ports are drawn on the left side the cells are awkwardly arranged in a large column. Secondly the two-bit vector **y** requires breakout-boxes for its individual bits, resulting in an unnecessary complex diagram.

For the 2nd diagram Yosys has been given a description of the cell library as Verilog file containing blackbox modules. There are two ways to load cell descriptions into Yosys: First the Verilog file for the cell library can be passed directly to the **show** command using the `-lib <filename>` option. Secondly it is possible to load cell libraries into the design with the `read_verilog -lib <filename>` command. The 2nd method has the great advantage that the library only needs to be loaded once and can then be used in all subsequent calls to the **show** command.

In addition to that, the 2nd diagram was generated after `splitnet -ports` was run on the design. This command splits all signal vectors into individual signal bits, which is often desirable when looking at gate-level circuits. The `-ports` option is required to also split module ports. Per default the command only operates on interior signals.

E.3.4 Miscellaneous notes

Per default the `show` command outputs a temporary dot file and launches `xdot` to display it. The options `-format`, `-viewer` and `-prefix` can be used to change format, viewer and filename prefix. Note that the `pdf` and `ps` format are the only formats that support plotting multiple modules in one run.

In densely connected circuits it is sometimes hard to keep track of the individual signal wires. For this cases it can be useful to call `show` with the `-colors <integer>` argument, which randomly assigns colors to the nets. The integer (> 0) is used as seed value for the random color assignments. Sometimes it is necessary it try some values to find an assignment of colors that looks good.

The command `help show` prints a complete listing of all options supported by the `show` command.

E.4 Navigating the design

Plotting circuit diagrams for entire modules in the design brings us only helps in simple cases. For complex modules the generated circuit diagrams are just stupidly big and are no help at all. In such cases one first has to select the relevant portions of the circuit.

In addition to *what* to display one also needs to carefully decide *when* to display it, with respect to the synthesis flow. In general it is a good idea to troubleshoot a circuit in the earliest state in which a problem can be reproduced. So if, for example, the internal state before calling the `techmap` command already fails to verify, it is better to troubleshoot the coarse-grain version of the circuit before `techmap` than the gate-level circuit after `techmap`.

Note: It is generally recommended to verify the internal state of a design by writing it to a Verilog file using `write_verilog -noexpr` and using the simulation models from `simlib.v` and `simcells.v` from the Yosys data directory (as printed by `yosys-config --datdir`).

E.4.1 Interactive navigation

Listing 5.3: Demonstration of `ls` and `cd` using `example.v` from Listing 5.1

```
yosys> ls

1 modules:
  example

yosys> cd example

yosys [example]> ls

7 wires:
  $0\y[1:0]
  $add$example.v:5$2_Y
  a
  b
  c
  clk
```

(continues on next page)

(continued from previous page)

```
y

3 cells:
  $add$example.v:5$2
  $procdff$7
  $procmux$5
```

Listing 5.4: Output of `dump \ $2` using the design from Listing 5.1 and Fig. 5.1

```
attribute \src "example.v:5"
cell $add $add$example.v:5$2
  parameter \A_SIGNED 0
  parameter \A_WIDTH 1
  parameter \B_SIGNED 0
  parameter \B_WIDTH 1
  parameter \Y_WIDTH 2
  connect \A \a
  connect \B \b
  connect \Y $add$example.v:5$2_Y
end
```

Once the right state within the synthesis flow for debugging the circuit has been identified, it is recommended to simply add the `shell` command to the matching place in the synthesis script. This command will stop the synthesis at the specified moment and go to shell mode, where the user can interactively enter commands.

For most cases, the shell will start with the whole design selected (i.e. when the synthesis script does not already narrow the selection). The command `ls` can now be used to create a list of all modules. The command `cd` can be used to switch to one of the modules (type `cd ..` to switch back). Now the `ls` command lists the objects within that module. Listing 5.3 demonstrates this using the design from Listing 5.1.

There is a thing to note in Listing 5.3: We can see that the cell names from Fig. 5.1 are just abbreviations of the actual cell names, namely the part after the last dollar-sign. Most auto-generated names (the ones starting with a dollar sign) are rather long and contains some additional information on the origin of the named object. But in most cases those names can simply be abbreviated using the last part.

Usually all interactive work is done with one module selected using the `cd` command. But it is also possible to work from the design-context (`cd ..`). In this case all object names must be prefixed with `<module_name>/.`. For example `a*/b*` would refer to all objects whose names start with `b` from all modules whose names start with `a`.

The `dump` command can be used to print all information about an object. For example `dump $2` will print Listing 5.4. This can for example be useful to determine the names of nets connected to cells, as the net-names are usually suppressed in the circuit diagram if they are auto-generated.

For the remainder of this document we will assume that the commands are run from module-context and not design-context.

E.4.2 Working with selections

Fig. 5.4: Output of `show` after `select $2` or `select t:$add` (see also Fig. 5.1)

When a module is selected using the `cd` command, all commands (with a few exceptions, such as the `read_` and `write_` commands) operate only on the selected module. This can also be useful for synthesis scripts where different synthesis strategies should be applied to different modules in the design.

But for most interactive work we want to further narrow the set of selected objects. This can be done using the `select` command.

For example, if the command `select $2` is executed, a subsequent `show` command will yield the diagram shown in Fig. 5.4. Note that the nets are now displayed in ellipses. This indicates that they are not selected, but only shown because the diagram contains a cell that is connected to the net. This of course makes no difference for the circuit that is shown, but it can be a useful information when manipulating selections.

Objects can not only be selected by their name but also by other properties. For example `select t:$add` will select all cells of type `$add`. In this case this is also yields the diagram shown in Fig. 5.4.

Listing 5.5: Test module for operations on selections

```

module foobaraddsub(a, b, c, d, fa, fs, ba, bs);
  input [7:0] a, b, c, d;
  output [7:0] fa, fs, ba, bs;
  assign fa = a + (* foo *) b;
  assign fs = a - (* foo *) b;
  assign ba = c + (* bar *) d;
  assign bs = c - (* bar *) d;
endmodule

```

The output of `help select` contains a complete syntax reference for matching different properties.

Many commands can operate on explicit selections. For example the command `dump t:$add` will print information on all `$add` cells in the active module. Whenever a command has `[selection]` as last argument in its usage help, this means that it will use the engine behind the `select` command to evaluate additional arguments and use the resulting selection instead of the selection created by the last `select` command.

Normally the `select` command overwrites a previous selection. The commands `select -add` and `select -del` can be used to add or remove objects from the current selection.

The command `select -clear` can be used to reset the selection to the default, which is a complete selection of everything in the current module.

E.4.3 Operations on selections

Listing 5.6: Another test module for operations on selections

```

module sumprod(a, b, c, sum, prod);

  input [7:0] a, b, c;
  output [7:0] sum, prod;

  /* sumstuff */
  assign sum = a + b + c;
  /* */

  assign prod = a * b * c;

endmodule

```

Fig. 5.5: Output of `show a:sumstuff` on Listing 5.6

The `select` command is actually much more powerful than it might seem on the first glimpse. When it is called with multiple arguments, each argument is evaluated and pushed separately on a stack. After all arguments have been processed it simply creates the union of all elements on the stack. So the following command will select all `$add` cells and all objects with the `foo` attribute set:

```

select t:$add a:foo

```

(Try this with the design shown in Listing 5.5. Use the `select -list` command to list the current selection.)

In many cases simply adding more and more stuff to the selection is an ineffective way of selecting the interesting part of the design. Special arguments can be used to combine the elements on the stack. For

example the `%i` arguments pops the last two elements from the stack, intersects them, and pushes the result back on the stack. So the following command will select all `$add` cells that have the `foo` attribute set:

```
select t:$add a:foo %i
```

The listing in [Listing 5.6](#) uses the Yosys non-standard `{... *}` syntax to set the attribute `sumstuff` on all cells generated by the first assign statement. (This works on arbitrary large blocks of Verilog code and can be used to mark portions of code for analysis.)

Selecting `a:sumstuff` in this module will yield the circuit diagram shown in [Fig. 5.5](#). As only the cells themselves are selected, but not the temporary wire `$1_Y`, the two adders are shown as two disjunct parts. This can be very useful for global signals like clock and reset signals: just unselect them using a command such as `select -del clk rst` and each cell using them will get its own net label.

In this case however we would like to see the cells connected properly. This can be achieved using the `%x` action, that broadens the selection, i.e. for each selected wire it selects all cells connected to the wire and vice versa. So `show a:sumstuff %x` yields the diagram shown in [Fig. 5.6](#).

Fig. 5.6: Output of `show a:sumstuff %x` on [Listing 5.6](#)

E.4.4 Selecting logic cones

[Fig. 5.6](#) shows what is called the **input cone** of `sum`, i.e. all cells and signals that are used to generate the signal `sum`. The `%ci` action can be used to select the input cones of all object in the top selection in the stack maintained by the `select` command.

As the `%x` action, this command broadens the selection by one “step”. But this time the operation only works against the direction of data flow. That means, wires only select cells via output ports and cells only select wires via input ports.

[Fig. 5.7](#) show the sequence of diagrams generated by the following commands:

```
show prod
show prod %ci
show prod %ci %ci
show prod %ci %ci %ci
```

When selecting many levels of logic, repeating `%ci` over and over again can be a bit dull. So there is a shortcut for that: the number of iterations can be appended to the action. So for example the action `%ci3` is identical to performing the `%ci` action three times.

The action `%ci*` performs the `%ci` action over and over again until it has no effect anymore.

Fig. 5.7: Objects selected by `select prod \%ci...`

In most cases there are certain cell types and/or ports that should not be considered for the `%ci` action, or we only want to follow certain cell types and/or ports. This can be achieved using additional patterns that can be appended to the `%ci` action.

Lets consider the design from Listing 5.7. It serves no purpose other than being a non-trivial circuit for demonstrating some of the advanced Yosys features. We synthesize the circuit using `proc; opt; memory;` and change to the `memdemo` module with `cd memdemo`. If we type `show` now we see the diagram shown in Fig. 5.8.

Listing 5.7: Demo circuit for demonstrating some advanced Yosys features

```
module memdemo(clk, d, y);
input clk;
input [3:0] d;
output reg [3:0] y;
```

(continues on next page)

(continued from previous page)

```

integer i;
reg [1:0] s1, s2;
reg [3:0] mem [0:3];

always @(posedge clk) begin
    for (i = 0; i < 4; i = i+1)
        mem[i] <= mem[(i+1) % 4] + mem[(i+2) % 4];
    { s2, s1 } = d ? { s1, s2 } ^ d : 4'b0;
    mem[s1] <= d;
    y <= mem[s2];
end

endmodule

```

Fig. 5.8: Complete circuit diagram for the design shown in Listing 5.7

But maybe we are only interested in the tree of multiplexers that select the output value. In order to get there, we would start by just showing the output signal and its immediate predecessors:

```
show y %ci2
```

From this we would learn that `y` is driven by a `$dff` cell, that `y` is connected to the output port `Q`, that the `clk` signal goes into the `CLK` input port of the cell, and that the data comes from an auto-generated wire into the input `D` of the flip-flop cell.

As we are not interested in the clock signal we add an additional pattern to the `%ci` action, that tells it to only follow ports `Q` and `D` of `$dff` cells:

```
show y %ci2:+$dff[Q,D]
```

To add a pattern we add a colon followed by the pattern to the `%ci` action. The pattern itself starts with `-` or `+`, indicating if it is an include or exclude pattern, followed by an optional comma separated list of cell types, followed by an optional comma separated list of port names in square brackets.

Since we know that the only cell considered in this case is a `$dff` cell, we could as well only specify the port names:

```
show y %ci2:+[Q,D]
```

Or we could decide to tell the `%ci` action to not follow the `CLK` input:

```
show y %ci2:-[CLK]
```

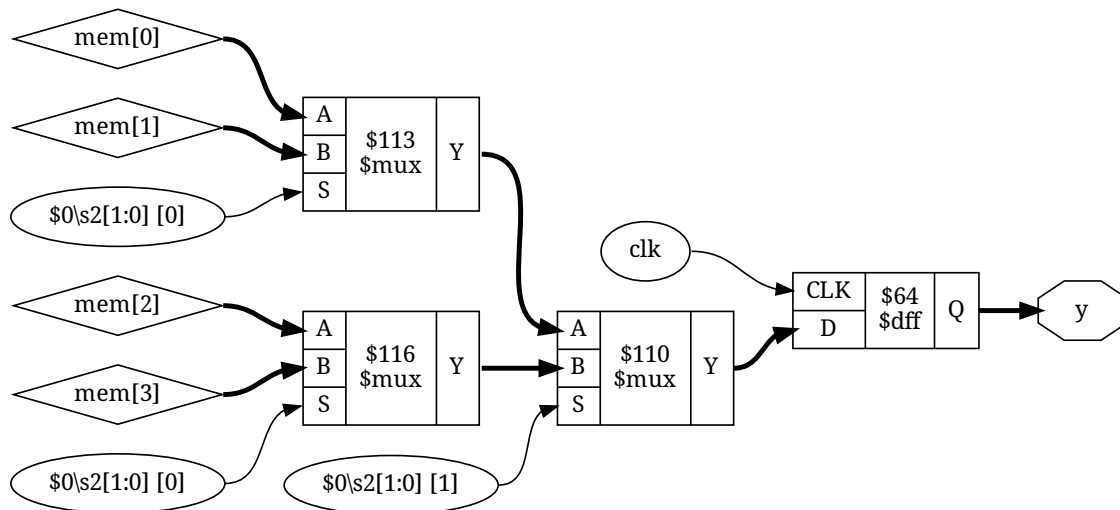

Fig. 5.9: Output of `show y %ci2:+$dff[Q,D] %ci*:-$mux[S] :-$dff`

Next we would investigate the next logic level by adding another `%ci2` to the command:

```
show y %ci2:-[CLK] %ci2
```

From this we would learn that the next cell is a `$mux` cell and we would add additional pattern to narrow the selection on the path we are interested. In the end we would end up with a command such as

```
show y %ci2:+$dff[Q,D] %ci*:-$mux[S] :-$dff
```

in which the first `%ci` jumps over the initial d-type flip-flop and the 2nd action selects the entire input cone without going over multiplexer select inputs and flip-flop cells. The diagram produces by this command is shown in Fig. 5.9.

Similar to `%ci` exists an action `%co` to select output cones that accepts the same syntax for pattern and repetition. The `%x` action mentioned previously also accepts this advanced syntax.

This actions for traversing the circuit graph, combined with the actions for boolean operations such as intersection (`%i`) and difference (`%d`) are powerful tools for extracting the relevant portions of the circuit under investigation.

See `help select` for a complete list of actions available in selections.

E.4.5 Storing and recalling selections

The current selection can be stored in memory with the command `select -set <name>`. It can later be recalled using `select @<name>`. In fact, the `@<name>` expression pushes the stored selection on the stack maintained by the `select` command. So for example

```
select @foo @bar %i
```

will select the intersection between the stored selections `foo` and `bar`.

In larger investigation efforts it is highly recommended to maintain a script that sets up relevant selections, so they can easily be recalled, for example when Yosys needs to be re-run after a design or source code change.

The `history` command can be used to list all recent interactive commands. This feature can be useful for creating such a script from the commands used in an interactive session.

E.5 Advanced investigation techniques

When working with very large modules, it is often not enough to just select the interesting part of the module. Instead it can be useful to extract the interesting part of the circuit into a separate module. This can for example be useful if one wants to run a series of synthesis commands on the critical part of the module and wants to carefully read all the debug output created by the commands in order to spot a problem. This kind of troubleshooting is much easier if the circuit under investigation is encapsulated in a separate module.

Listing 5.8 shows how the `submod` command can be used to split the circuit from Listing 5.7 and Fig. 5.8 into its components. The `-name` option is used to specify the name of the new module and also the name of the new cell in the current module.

Listing 5.8: The circuit from Listing 5.7 and Fig. 5.8 broken up using `submod`

```
select -set outstage y %ci2:+$dff[Q,D] %ci*:-$mux[S]:-$dff
select -set selstage y %ci2:+$dff[Q,D] %ci*:-$dff @outstage %d
select -set scramble mem* %ci2 %ci*:-$dff mem* %d @selstage %d
submod -name scramble @scramble
submod -name outstage @outstage
submod -name selstage @selstage
```

E.5.1 Evaluation of combinatorial circuits

The `eval` command can be used to evaluate combinatorial circuits. For example (see Listing 5.8 for the circuit diagram of `selstage`):

```
yosys [selstage]> eval -set s2,s1 4'b1001 -set d 4'hc -show n2 -show n1

1. Executing EVAL pass (evaluate the circuit given an input).
Full command line: eval -set s2,s1 4'b1001 -set d 4'hc -show n2 -show n1
Eval result: \n2 = 2'10.
Eval result: \n1 = 2'10.
```

So the `-set` option is used to set input values and the `-show` option is used to specify the nets to evaluate. If no `-show` option is specified, all selected output ports are used per default.

If a necessary input value is not given, an error is produced. The option `-set-undef` can be used to instead set all unspecified input nets to undef (x).

The `-table` option can be used to create a truth table. For example:

```
yosys [selstage]> eval -set-undef -set d[3:1] 0 -table s1,d[0]
```

10. Executing EVAL pass (evaluate the circuit given an input).

Full command line: `eval -set-undef -set d[3:1] 0 -table s1,d[0]`

\s1	\d [0]		\n1	\n2
----	-----		----	----
2'00	1'0		2'00	2'00
2'00	1'1		2'xx	2'00
2'01	1'0		2'00	2'00
2'01	1'1		2'xx	2'01
2'10	1'0		2'00	2'00
2'10	1'1		2'xx	2'10
2'11	1'0		2'00	2'00
2'11	1'1		2'xx	2'11

Assumed undef (x) value for the following signals: \s2

Note that the `eval` command (as well as the `sat` command discussed in the next sections) does only operate on flattened modules. It can not analyze signals that are passed through design hierarchy levels. So the `flatten` command must be used on modules that instantiate other modules before this commands can be applied.

E.5.2 Solving combinatorial SAT problems

Listing 5.9: A simple miter circuit for testing if a number is prime.

But it has a problem (see main text and [Listing 5.10](#)).

```
module primetest(p, a, b, ok);
input [15:0] p, a, b;
output ok = p != a*b || a == 1 || b == 1;
endmodule
```

Listing 5.10: Experiments with the miter circuit from [Listing 5.9](#).

The first attempt of proving that 31 is prime failed because the SAT solver found a creative way of factorizing 31 using integer overflow.

```
yosys [primetest]> sat -prove ok 1 -set p 31
```

8. Executing SAT pass (solving SAT problems in the circuit).

Full command line: `sat -prove ok 1 -set p 31`

Setting up SAT problem:

Import set-constraint: \p = 16'0000000000011111

Final constraint equation: \p = 16'0000000000011111

Imported 6 cells to SAT database.

Import proof-constraint: \ok = 1'1

(continues on next page)

(continued from previous page)

Final proof equation: $\log k = 1'1$

Solving problem with 2790 variables and 8241 clauses..

SAT proof finished - model found: FAIL!

9. Executing SAT pass (solving SAT problems in the circuit).

```
Full command line: sat -prove ok 1 -set p 31 -set a[15:8],b[15:8] 0
```

Setting up SAT problem:

```
Import set-constraint: \p = 16'00000000000011111
```

```
Import set-constraint: { \a [15:8] \b [15:8] } = 16'0000000000000000
```

Final constraint equation: $\{ \text{\texttt{a [15:8] b [15:8] p}} \} = \{ 16'0000000000000000 \ 16'00000000000011111 \}$

Imported 6 cells to SAT database.

```
Import proof-constraint: \ok = 1'1
```

Final proof equation: $\text{ok} = 1'1$

Solving problem with 2790 variables and 8257 clauses..

```
SAT proof finished - no model found: SUCCESS!
```

\	\	\

Often the opposite of the `eval` command is needed, i.e. the circuits output is given and we want to find the matching input signals. For small circuits with only a few input bits this can be accomplished by trying all possible input combinations, as it is done by the `eval -table` command. For larger circuits however, Yosys provides the `sat` command that uses a SAT solver, [MiniSAT](#), to solve this kind of problems.

The `sat` command works very similar to the `eval` command. The main difference is that it is now also

possible to set output values and find the corresponding input values. For Example:

```
yosys [selstage]> sat -show s1,s2,d -set s1 s2 -set n2,n1 4'b1001
```

11. Executing SAT pass (solving SAT problems in the circuit).

Full command line: `sat -show s1,s2,d -set s1 s2 -set n2,n1 4'b1001`

Setting up SAT problem:

Import set-constraint: `\s1 = \s2`

Import set-constraint: `{ \n2 \n1 } = 4'b1001`

Final constraint equation: `{ \n2 \n1 \s1 } = { 4'b1001 \s2 }`

Imported 3 cells to SAT database.

Import show expression: `{ \s1 \s2 \d }`

Solving problem with 81 variables and 207 clauses..

SAT solving finished - model found:

Signal Name	Dec	Hex	Bin
-----	-----	-----	-----
\d	9	9	1001
\s1	0	0	00
\s2	0	0	00

Note that the `sat` command supports signal names in both arguments to the `-set` option. In the above example we used `-set s1 s2` to constraint `s1` and `s2` to be equal. When more complex constraints are needed, a wrapper circuit must be constructed that checks the constraints and signals if the constraint was met using an extra output port, which then can be forced to a value using the `-set` option. (Such a circuit that contains the circuit under test plus additional constraint checking circuitry is called a *miter* circuit.)

[Listing 5.9](#) shows a miter circuit that is supposed to be used as a prime number test. If `ok` is 1 for all input values `a` and `b` for a given `p`, then `p` is prime, or at least that is the idea.

The Yosys shell session shown in [Listing 5.10](#) demonstrates that SAT solvers can even find the unexpected solutions to a problem: Using integer overflow there actually is a way of “factorizing” 31. The clean solution would of course be to perform the test in 32 bits, for example by replacing `p != a*b` in the miter with `p != {16'd0,a}b`, or by using a temporary variable for the 32 bit product `a*b`. But as 31 fits well into 8 bits (and as the purpose of this document is to show off Yosys features) we can also simply force the upper 8 bits of `a` and `b` to zero for the `sat` call, as is done in the second command in [Listing 5.10](#) (line 31).

The `-prove` option used in this example works similar to `-set`, but tries to find a case in which the two arguments are not equal. If such a case is not found, the property is proven to hold for all inputs that satisfy the other constraints.

It might be worth noting, that SAT solvers are not particularly efficient at factorizing large numbers. But if a small factorization problem occurs as part of a larger circuit problem, the Yosys SAT solver is perfectly capable of solving it.

E.5.3 Solving sequential SAT problems

Listing 5.11: Solving a sequential SAT problem in the memdemo module from [Listing 5.7](#).

```
yosys [memdemo]> sat -seq 6 -show y -show d -set-init-undef \
-max_undef -set-at 4 y 1 -set-at 5 y 2 -set-at 6 y 3

6. Executing SAT pass (solving SAT problems in the circuit).
Full command line: sat -seq 6 -show y -show d -set-init-undef
-max_undef -set-at 4 y 1 -set-at 5 y 2 -set-at 6 y 3

Setting up time step 1:
Final constraint equation: { } = { }
Imported 29 cells to SAT database.

Setting up time step 2:
Final constraint equation: { } = { }
Imported 29 cells to SAT database.

Setting up time step 3:
Final constraint equation: { } = { }
Imported 29 cells to SAT database.

Setting up time step 4:
Import set-constraint for timestep: \y = 4'0001
Final constraint equation: \y = 4'0001
Imported 29 cells to SAT database.

Setting up time step 5:
Import set-constraint for timestep: \y = 4'0010
Final constraint equation: \y = 4'0010
Imported 29 cells to SAT database.

Setting up time step 6:
Import set-constraint for timestep: \y = 4'0011
Final constraint equation: \y = 4'0011
Imported 29 cells to SAT database.

Setting up initial state:
Final constraint equation: { \y \s2 \s1 \mem[3] \mem[2] \mem[1]
\mem[0] } = 24'xxxxxxxxxxxxxxxxxxxxxxxxxxxx

Import show expression: \y
Import show expression: \d

Solving problem with 10322 variables and 27881 clauses..
SAT model found. maximizing number of undefs.
SAT solving finished - model found:
```

Time	Signal Name	Dec	Hex	Bin
init	\mem[0]	--	--	xxxx

(continues on next page)

(continued from previous page)

init \mem[1]	--	--	xxxx
init \mem[2]	--	--	xxxx
init \mem[3]	--	--	xxxx
init \s1	--	--	xx
init \s2	--	--	xx
init \y	--	--	xxxx

1 \d	0	0	0000
1 \y	--	--	xxxx

2 \d	1	1	0001
2 \y	--	--	xxxx

3 \d	2	2	0010
3 \y	0	0	0000

4 \d	3	3	0011
4 \y	1	1	0001

5 \d	--	--	001x
5 \y	2	2	0010

6 \d	--	--	xxxx
6 \y	3	3	0011

The SAT solver functionality in Yosys can not only be used to solve combinatorial problems, but can also solve sequential problems. Let's consider the entire memdemo module from [Listing 5.7](#) and suppose we want to know which sequence of input values for `d` will cause the output `y` to produce the sequence 1, 2, 3 from any initial state. [Listing 5.11](#) show the solution to this question, as produced by the following command:

```
sat -seq 6 -show y -show d -set-init-undef \
    -max_undef -set-at 4 y 1 -set-at 5 y 2 -set-at 6 y 3
```

The `-seq 6` option instructs the `sat` command to solve a sequential problem in 6 time steps. (Experiments with lower number of steps have show that at least 3 cycles are necessary to bring the circuit in a state from which the sequence 1, 2, 3 can be produced.)

The `-set-init-undef` option tells the `sat` command to initialize all registers to the undef (`x`) state. The way the `x` state is treated in Verilog will ensure that the solution will work for any initial state.

The `-max_undef` option instructs the `sat` command to find a solution with a maximum number of undefs. This way we can see clearly which inputs bits are relevant to the solution.

Finally the three `-set-at` options add constraints for the `y` signal to play the 1, 2, 3 sequence, starting with time step 4.

It is not surprising that the solution sets `d = 0` in the first step, as this is the only way of setting the `s1` and `s2` registers to a known value. The input values for the other steps are a bit harder to work out manually, but the SAT solver finds the correct solution in an instant.

There is much more to write about the `sat` command. For example, there is a set of options that can be used to performs sequential proofs using temporal induction [[EenSorensen03](#)]. The command `help sat` can be used to print a list of all options with short descriptions of their functions.

E.6 Conclusion

Yosys provides a wide range of functions to analyze and investigate designs. For many cases it is sufficient to simply display circuit diagrams, maybe use some additional commands to narrow the scope of the circuit diagrams to the interesting parts of the circuit. But some cases require more than that. For this applications Yosys provides commands that can be used to further inspect the behavior of the circuit, either by evaluating which output values are generated from certain input values (`eval`) or by evaluation which input values and initial conditions can result in a certain behavior at the outputs (`sat`). The SAT command can even be used to prove (or disprove) theorems regarding the circuit, in more advanced cases with the additional help of a miter circuit.

This features can be powerful tools for the circuit designer using Yosys as a utility for building circuits and the software developer using Yosys as a framework for new algorithms alike.

012: CONVERTING VERILOG TO BTOR PAGE

F.1 Installation

Yosys written in C++ (using features from C++11) and is tested on modern Linux. It should compile fine on most UNIX systems with a C++11 compiler. The README file contains useful information on building Yosys and its prerequisites.

Yosys is a large and feature-rich program with some dependencies. For this work, we may deactivate other extra features such as TCL and ABC support in the Makefile.

This Application Note is based on [Yosys GIT Rev. 082550f](#) from 2015-04-04.

F.2 Quick start

We assume that the Verilog design is synthesizable and we also assume that the design does not have multi-dimensional memories. As BTOR implicitly initializes registers to zero value and memories stay uninitialized, we assume that the Verilog design does not contain initial blocks. For more details about the BTOR format, please refer to [\[BBL08\]](#).

We provide a shell script `verilog2btor.sh` which can be used to convert a Verilog design to BTOR. The script can be found in the `backends/btor` directory. The following example shows its usage:

```
verilog2btor.sh fsm.v fsm.btor test
```

The script `verilog2btor.sh` takes three parameters. In the above example, the first parameter `fsm.v` is the input design, the second parameter `fsm.btor` is the file name of BTOR output, and the third parameter `test` is the name of top module in the design.

To specify the properties (that need to be checked), we have two options:

- We can use the Verilog `assert` statement in the procedural block or module body of the Verilog design, as shown in [Listing 6.1](#). This is the preferred option.
- We can use a single-bit output wire, whose name starts with `safety`. The value of this output wire needs to be driven low when the property is met, i.e. the solver will try to find a model that makes the safety pin go high. This is demonstrated in [Listing 6.2](#).

Listing 6.1: Specifying property in Verilog design with `assert`

```
module test(input clk, input rst, output y);  
  
    reg [2:0] state;
```

(continues on next page)

(continued from previous page)

```
always @(posedge clk) begin
    if (rst || state == 3) begin
        state <= 0;
    end else begin
        assert(state < 3);
        state <= state + 1;
    end
end

assign y = state[2];

assert property (y != 1'b1);

endmodule
```

Listing 6.2: Specifying property in Verilog design with output wire

```
module test(input clk, input rst,
            output y, output safety1);

    reg [2:0] state;

    always @(posedge clk) begin
        if (rst || state == 3)
            state <= 0;
        else
            state <= state + 1;
    end

    assign y = state[2];

    assign safety1 = !(y != 1'b1);

endmodule
```

We can run [Boolector 1.4.1](#)¹ on the generated BTOR file:

```
$ boolector fsm.btor
unsat
```

We can also use [nuXmv](#), but on BTOR designs it does not support memories yet. With the next release of nuXmv, we will be also able to verify designs with memories.

¹ Newer version of Boolector do not support sequential models. Boolector 1.4.1 can be built with picosat-951. Newer versions of picosat have an incompatible API.

F.3 Detailed flow

Yosys is able to synthesize Verilog designs up to the gate level. We are interested in keeping registers and memories when synthesizing the design. For this purpose, we describe a customized Yosys synthesis flow, that is also provided by the `verilog2btor.sh` script. Listing 6.3 shows the Yosys commands that are executed by `verilog2btor.sh`.

Listing 6.3: Synthesis Flow for BTOR with memories

```
read_verilog -sv $1;
hierarchy -top $3; hierarchy -libdir $DIR;
hierarchy -check;
proc; opt;
opt_expr -mux_undef; opt;
rename -hide;;;
splice; opt;
memory_dff -wr_only; memory_collect;;
flatten;;
memory_unpack;
splitnets -driver;
setundef -zero -undriven;
opt;;;
write_btor $2;
```

Here is short description of what is happening in the script line by line:

1. Reading the input file.
2. Setting the top module in the hierarchy and trying to read automatically the files which are given as `include` in the file read in first line.
3. Checking the design hierarchy.
4. Converting processes to multiplexers (muxs) and flip-flops.
5. Removing undef signals from muxs.
6. Hiding all signal names that are not used as module ports.
7. Explicit type conversion, by introducing slice and concat cells in the circuit.
8. Converting write memories to synchronous memories, and collecting the memories to multi-port memories.
9. Flattening the design to get only one module.
10. Separating read and write memories.
11. Splitting the signals that are partially assigned
12. Setting undef to zero value.
13. Final optimization pass.
14. Writing BTOR file.

For detailed description of the commands mentioned above, please refer to the Yosys documentation, or run `yosys -h <command_name>`.

The script presented earlier can be easily modified to have a BTOR file that does not contain memories. This is done by removing the line number 8 and 10, and introduces a new command `memory` at line number 8. Listing 6.4 shows the modified Yosys script file:

Listing 6.4: Synthesis Flow for BTOR without memories

```

read_verilog -sv $1;
hierarchy -top $3; hierarchy -libdir $DIR;
hierarchy -check;
proc; opt;
opt_expr -mux_undef; opt;
rename -hide;;;
splice; opt;
memory;;
flatten;;
splitnets -driver;
setundef -zero -undriven;
opt;;;
write_btor $2;

```

F.4 Example

Here is an example Verilog design that we want to convert to BTOR:

Listing 6.5: Example - Verilog Design

```

module array(input clk);

    reg [7:0] counter;
    reg [7:0] mem [7:0];

    always @(posedge clk) begin
        counter <= counter + 8'd1;
        mem[counter] <= counter;
    end

    assert property (!(counter > 8'd0) ||
        mem[counter - 8'd1] == counter - 8'd1);

endmodule

```

The generated BTOR file that contain memories, using the script shown in [Listing 6.6](#):

Listing 6.6: Example - Converted BTOR with memory

```

1 var 1 clk
2 array 8 3
3 var 8 $auto$rename.cc:150:execute$20
4 const 8 00000001
5 sub 8 3 4
6 slice 3 5 2 0
7 read 8 2 6
8 slice 3 3 2 0
9 add 8 3 4
10 const 8 00000000

```

(continues on next page)

(continued from previous page)

```

11 ugt 1 3 10
12 not 1 11
13 const 8 11111111
14 slice 1 13 0 0
15 one 1
16 eq 1 1 15
17 and 1 16 14
18 write 8 3 2 8 3
19 acond 8 3 17 18 2
20 anext 8 3 2 19
21 eq 1 7 5
22 or 1 12 21
23 const 1 1
24 one 1
25 eq 1 23 24
26 cond 1 25 22 24
27 root 1 -26
28 cond 8 1 9 3
29 next 8 3 28

```

And the BTOR file obtained by the script shown in [Listing 6.7](#), which expands the memory into individual elements:

Listing 6.7: Example - Converted BTOR with memory

```

1 var 1 clk
2 var 8 mem[0]
3 var 8 $auto$rename.cc:150:execute$20
4 slice 3 3 2 0
5 slice 1 4 0 0
6 not 1 5
7 slice 1 4 1 1
8 not 1 7
9 slice 1 4 2 2
10 not 1 9
11 and 1 8 10
12 and 1 6 11
13 cond 8 12 3 2
14 cond 8 1 13 2
15 next 8 2 14
16 const 8 00000001
17 add 8 3 16
18 const 8 00000000
19 ugt 1 3 18
20 not 1 19
21 var 8 mem[2]
22 and 1 7 10
23 and 1 6 22
24 cond 8 23 3 21
25 cond 8 1 24 21
26 next 8 21 25
27 sub 8 3 16

```

(continues on next page)

(continued from previous page)

```
...  
54 cond 1 53 50 52  
55 root 1 -54  
  
...  
77 cond 8 76 3 44  
78 cond 8 1 77 44  
79 next 8 44 78
```

F.5 Limitations

BTOR does not support initialization of memories and registers, i.e. they are implicitly initialized to value zero, so the initial block for memories need to be removed when converting to BTOR. It should also be kept in consideration that BTOR does not support the **x** or **z** values of Verilog.

Another thing to bear in mind is that Yosys will convert multi-dimensional memories to one-dimensional memories and address decoders. Therefore out-of-bounds memory accesses can yield unexpected results.

F.6 Conclusion

Using the described flow, we can use Yosys to generate word-level verification benchmarks with or without memories from Verilog designs.

COMMAND LINE REFERENCE

G.1 abc - use ABC for technology mapping

```
abc [options] [selection]
```

This pass uses the ABC tool [1] for technology mapping of yosys's internal gate library to a target architecture.

```
-exe <command>
```

use the specified command instead of "<yosys-bindir>/yosys-abc" to execute ABC. This can e.g. be used to call a specific version of ABC or a wrapper.

```
-script <file>
```

use the specified ABC script file instead of the default script.

if <file> starts with a plus sign (+), then the rest of the filename string is interpreted as the command string to be passed to ABC. The leading plus sign is removed and all commas (,) in the string are replaced with blanks before the string is passed to ABC.

if no -script parameter is given, the following scripts are used:

```
for -liberty/-genlib without -constr:
```

```
    strash; &get -n; &fraig -x; &put; scorr; dc2; dretime; strash;
    &get -n; &dch -f; &nf {D}; &put
```

```
for -liberty/-genlib with -constr:
```

```
    strash; &get -n; &fraig -x; &put; scorr; dc2; dretime; strash;
    &get -n; &dch -f; &nf {D}; &put; buffer; upsize {D};
    dnsiz {D}; stime -p
```

```
for -lut/-luts (only one LUT size):
```

```
    strash; &get -n; &fraig -x; &put; scorr; dc2; dretime; strash;
    dch -f; if; mfs2; lutpack {S}
```

```
for -lut/-luts (different LUT sizes):
```

```
    strash; &get -n; &fraig -x; &put; scorr; dc2; dretime; strash;
    dch -f; if; mfs2
```

```
for -sop:
```

(continues on next page)

(continued from previous page)

```

    strash; &get -n; &fraig -x; &put; scorr; dc2; dretime; strash;
    dch -f; cover {I} {P}

otherwise:
    strash; &get -n; &fraig -x; &put; scorr; dc2; dretime; strash;
    &get -n; &dch -f; &nf {D}; &put

-fast
use different default scripts that are slightly faster (at the cost
of output quality):

for -liberty/-genlib without -constr:
    strash; dretime; map {D}

for -liberty/-genlib with -constr:
    strash; dretime; map {D}; buffer; upsize {D}; dnsiz {D};
    stime -p

for -lut/-luts:
    strash; dretime; if

for -sop:
    strash; dretime; cover {I} {P}

otherwise:
    strash; dretime; map

-liberty <file>
generate netlists for the specified cell library (using the liberty
file format).

-genlib <file>
generate netlists for the specified cell library (using the SIS Genlib
file format).

-constr <file>
pass this file with timing constraints to ABC.
use with -liberty/-genlib.

a constr file contains two lines:
    set_driving_cell <cell_name>
    set_load <floating_point_number>

the set_driving_cell statement defines which cell type is assumed to
drive the primary inputs and the set_load statement sets the load in
femtofarads for each primary output.

-D <picoseconds>
set delay target. the string {D} in the default scripts above is
replaced by this option when used, and an empty string otherwise.
this also replaces 'dretime' with 'dretime; retime -o {D}' in the
default scripts above.

```

(continues on next page)

(continued from previous page)

```

-I <num>
    maximum number of SOP inputs.
    (replaces {I} in the default scripts above)

-P <num>
    maximum number of SOP products.
    (replaces {P} in the default scripts above)

-S <num>
    maximum number of LUT inputs shared.
    (replaces {S} in the default scripts above, default: -S 1)

-lut <width>
    generate netlist using luts of (max) the specified width.

-lut <w1>:<w2>
    generate netlist using luts of (max) the specified width <w2>. All
    luts with width <= <w1> have constant cost. for luts larger than <w1>
    the area cost doubles with each additional input bit. the delay cost
    is still constant for all lut widths.

-luts <cost1>,<cost2>,<cost3>,<sizeN>:<cost4-N>,...
    generate netlist using luts. Use the specified costs for luts with 1,
    2, 3, .. inputs.

-sop
    map to sum-of-product cells and inverters

-g type1,type2,...
    Map to the specified list of gate types. Supported gates types are:
        AND, NAND, OR, NOR, XOR, XNOR, ANDNOT, ORNOT, MUX,
        NMUX, AOI3, OAI3, AOI4, OAI4.
    (The NOT gate is always added to this list automatically.)

    The following aliases can be used to reference common sets of gate
    types:
        simple: AND OR XOR MUX
        cmos2:  NAND NOR
        cmos3:  NAND NOR AOI3 OAI3
        cmos4:  NAND NOR AOI3 OAI3 AOI4 OAI4
        cmos:   NAND NOR AOI3 OAI3 AOI4 OAI4 NMUX MUX XOR XNOR
        gates:  AND NAND OR NOR XOR XNOR ANDNOT ORNOT
        aig:    AND NAND OR NOR ANDNOT ORNOT

    The alias 'all' represent the full set of all gate types.

    Prefix a gate type with a '-' to remove it from the list. For example
    the arguments 'AND,OR,XOR' and 'simple,-MUX' are equivalent.

    The default is 'all,-NMUX,-AOI3,-OAI3,-AOI4,-OAI4'.

```

(continues on next page)

(continued from previous page)

`-dff`
also pass `$_DFF_?` and `$_DFFE_??` cells through ABC. modules with many clock domains are automatically partitioned in clock domains and each domain is passed through ABC independently.

`-clk [!]<clock-signal-name>[, [!]<enable-signal-name>]`
use only the specified clock domain. this is like `-dff`, but only FF cells that belong to the specified clock domain are used.

`-keepff`
set the "keep" attribute on flip-flop output wires. (and thus preserve them, for example for equivalence checking.)

`-nocleanup`
when this option is used, the temporary files created by this pass are not removed. this is useful for debugging.

`-showtmp`
print the temp dir name in log. usually this is suppressed so that the command output is identical across runs.

`-markgroups`
set a 'abctgroup' attribute on all objects created by ABC. The value of this attribute is a unique integer for each ABC process started. This is useful for debugging the partitioning of clock domains.

`-dress`
run the 'dress' command after all other ABC commands. This aims to preserve naming by an equivalence check between the original and post-ABC netlists (experimental).

When no target cell library is specified the Yosys standard cell library is loaded into ABC before the ABC script is executed.

Note that this is a logic optimization pass within Yosys that is calling ABC internally. This is not going to "run ABC on your design". It will instead run ABC on logic snippets extracted from your design. You will not get any useful output when passing an ABC script that writes a file. Instead write your full design as BLIF file with `write_blif` and then load that into ABC externally if you want to use ABC to convert your design into another format.

[1] <http://www.eecs.berkeley.edu/~alanmi/abc/>

G.2 abc9 - use ABC9 for technology mapping

```
abc9 [options] [selection]
```

This script pass performs a sequence of commands to facilitate the use of the ABC tool [1] for technology mapping of the current design to a target FPGA architecture. Only fully-selected modules are supported.

```
-run <from_label>:<to_label>
```

only run the commands between the labels (see below). an empty from label is synonymous to 'begin', and empty to label is synonymous to the end of the command list.

```
-exe <command>
```

use the specified command instead of "<yosys-bindir>/yosys-abc" to execute ABC. This can e.g. be used to call a specific version of ABC or a wrapper.

```
-script <file>
```

use the specified ABC script file instead of the default script.

if <file> starts with a plus sign (+), then the rest of the filename string is interpreted as the command string to be passed to ABC. The leading plus sign is removed and all commas (,) in the string are replaced with blanks before the string is passed to ABC.

if no -script parameter is given, the following scripts are used:

```
&scorr; &sweep; &dc2; &dch -f; &ps; &if {C} {W} {D} {R} -v; &mfs
```

```
-fast
```

use different default scripts that are slightly faster (at the cost of output quality):

```
&if {C} {W} {D} {R} -v
```

```
-D <picoseconds>
```

set delay target. the string {D} in the default scripts above is replaced by this option when used, and an empty string otherwise (indicating best possible delay).

```
-lut <width>
```

generate netlist using luts of (max) the specified width.

```
-lut <w1>:<w2>
```

generate netlist using luts of (max) the specified width <w2>. All luts with width <= <w1> have constant cost. for luts larger than <w1> the area cost doubles with each additional input bit. the delay cost is still constant for all lut widths.

```
-lut <file>
```

pass this file with lut library to ABC.

```
-luts <cost1>,<cost2>,<cost3>,<sizeN>:<cost4-N>,..
```

generate netlist using luts. Use the specified costs for luts with 1,

(continues on next page)

(continued from previous page)

2, 3, .. inputs.

`-maxlut <width>`

when auto-generating the lut library, discard all luts equal to or greater than this size (applicable when neither `-lut` nor `-luts` is specified).

`-dff`

also pass `$_DFF_[NP]_` cells through to ABC. modules with many clock domains are supported and automatically partitioned by ABC.

`-nocleanup`

when this option is used, the temporary files created by this pass are not removed. this is useful for debugging.

`-showtmp`

print the temp dir name in log. usually this is suppressed so that the command output is identical across runs.

`-box <file>`

pass this file with box library to ABC.

Note that this is a logic optimization pass within Yosys that is calling ABC internally. This is not going to "run ABC on your design". It will instead run ABC on logic snippets extracted from your design. You will not get any useful output when passing an ABC script that writes a file. Instead write your full design as an XAIGER file with ``write_xaiger'` and then load that into ABC externally if you want to use ABC to convert your design into another format.

G.3 abc9_exe - use ABC9 for technology mapping

abc9_exe [options]

This pass uses the ABC tool [1] for technology mapping of the top module (according to the (* top *) attribute or if only one module is currently selected) to a target FPGA architecture.

-exe <command>

use the specified command instead of "<yosys-bindir>/yosys-abc" to execute ABC. This can e.g. be used to call a specific version of ABC or a wrapper.

-script <file>

use the specified ABC script file instead of the default script.

if <file> starts with a plus sign (+), then the rest of the filename string is interpreted as the command string to be passed to ABC. The leading plus sign is removed and all commas (,) in the string are replaced with blanks before the string is passed to ABC.

if no -script parameter is given, the following scripts are used:

&scorr; &swEEP; &dc2; &dch -f; &ps; &if {C} {W} {D} {R} -v; &mfs

-fast

use different default scripts that are slightly faster (at the cost of output quality):

&if {C} {W} {D} {R} -v

-D <picoseconds>

set delay target. the string {D} in the default scripts above is replaced by this option when used, and an empty string otherwise (indicating best possible delay).

-lut <width>

generate netlist using luts of (max) the specified width.

-lut <w1>:<w2>

generate netlist using luts of (max) the specified width <w2>. All luts with width <= <w1> have constant cost. for luts larger than <w1> the area cost doubles with each additional input bit. the delay cost is still constant for all lut widths.

-lut <file>

pass this file with lut library to ABC.

-luts <cost1>,<cost2>,<cost3>,<sizeN>:<cost4-N>,...

generate netlist using luts. Use the specified costs for luts with 1, 2, 3, .. inputs.

-showtmp

print the temp dir name in log. usually this is suppressed so that the

(continues on next page)

(continued from previous page)

command output is identical across runs.

`-box <file>`

pass this file with box library to ABC.

`-cwd <dir>`

use this as the current working directory, inside which the 'input.xaig' file is expected. temporary files will be created in this directory, and the mapped result will be written to 'output.aig'.

Note that this is a logic optimization pass within Yosys that is calling ABC internally. This is not going to "run ABC on your design". It will instead run ABC on logic snippets extracted from your design. You will not get any useful output when passing an ABC script that writes a file. Instead write your full design as BLIF file with `write_blif` and then load that into ABC externally if you want to use ABC to convert your design into another format.

[1] <http://www.eecs.berkeley.edu/~alanmi/abc/>

G.4 abc9_ops - helper functions for ABC9

`abc9_ops [options] [selection]`

This pass contains a set of supporting operations for use during ABC technology mapping, and is expected to be called in conjunction with other operations from the 'abc9' script pass. Only fully-selected modules are supported.

`-check`

check that the design is valid, e.g. (* abc9_box_id *) values are unique, (* abc9_carry *) is only given for one input/output port, etc.

`-prep_hier`

derive all used (* abc9_box *) or (* abc9_flop *) (if `-dff` option) whitebox modules. with (* abc9_flop *) modules, only those containing \$dff/\$_DFF_[NP]_ cells with zero initial state -- due to an ABC limitation -- will be derived.

`-prep_bypass`

create techmap rules in the '\$abc9_map' and '\$abc9_unmap' designs for bypassing sequential (* abc9_box *) modules using a combinatorial box (named *_abc9_byp). bypassing is necessary if sequential elements (e.g. \$dff, \$mem, etc.) are discovered inside so that any combinatorial paths will be correctly captured. this bypass box will only contain ports that are referenced by a simple path declaration (\$specify2 cell) inside a specify block.

`-prep_dff`

select all (* abc9_flop *) modules instantiated in the design and store in the named selection '\$abc9_flops'.

(continues on next page)

(continued from previous page)

```
-prep_dff_submod
    within (* abc9_flop *) modules, rewrite all edge-sensitive path
    declarations and $setup() timing checks ($specify3 and $specrule cells)
    that share a 'DST' port with the $_DFF_[NP]_Q port from this 'Q' port
    to the DFF's 'D' port. this is to prepare such specify cells to be moved
    into the flop box.

-prep_dff_unmap
    populate the '$abc9_unmap' design with techmap rules for mapping
    *_abc9_flop cells back into their derived cell types (where the rules
    created by -prep_hier will then map back to the original cell with
    parameters).

-prep_delays
    insert `$_ABC9_DELAY' blackbox cells into the design to account for
    certain required times.

-break_scc
    for an arbitrarily chosen cell in each unique SCC of each selected
    module (tagged with an (* abc9_scc_id = <int> *) attribute) interrupt
    all wires driven by this cell's outputs with a temporary
    $_ABC9_SCC_BREAKER cell to break the SCC.

-prep_xaiger
    prepare the design for XAIGER output. this includes computing the
    topological ordering of ABC9 boxes, as well as preparing the
    '$abc9_holes' design that contains the logic behaviour of ABC9
    whiteboxes.

-dff
    consider flop cells (those instantiating modules marked with
    (* abc9_flop *)) during -prep_{delays,xaiger,box}.

-prep_lut <maxlut>
    pre-compute the lut library by analysing all modules marked with
    (* abc9_lut=<area> *).

-write_lut <dst>
    write the pre-computed lut library to <dst>.

-prep_box
    pre-compute the box library by analysing all modules marked with
    (* abc9_box *).

-write_box <dst>
    write the pre-computed box library to <dst>.

-reintegrate
    for each selected module, re-intergrate the module '<module-name>$abc9'
    by first recovering ABC9 boxes, and then stitching in the remaining
    primary inputs and outputs.
```

G.5 add - add objects to the design

```
add <command> [selection]
```

This command adds objects to the design. It operates on all fully selected modules. So e.g. 'add -wire foo' will add a wire foo to all selected modules.

```
add {-wire|-input|-inout|-output} <name> <width> [selection]
```

Add a wire (input, inout, output port) with the given name and width. The command will fail if the object exists already and has different properties than the object to be created.

```
add -global_input <name> <width> [selection]
```

Like 'add -input', but also connect the signal between instances of the selected modules.

```
add {-assert|-assume|-live|-fair|-cover} <name1> [-if <name2>]
```

Add an \$assert, \$assume, etc. cell connected to a wire named name1, with its enable signal optionally connected to a wire named name2 (default: 1'b1).

```
add -mod <name[s]>
```

Add module[s] with the specified name[s].

G.6 aigmap - map logic to and-inverter-graph circuit

```
aigmap [options] [selection]
```

Replace all logic cells with circuits made of only \$_AND_ and \$_NOT_ cells.

```
-nand
```

Enable creation of \$_NAND_ cells

```
-select
```

Overwrite replaced cells in the current selection with new \$_AND_, \$_NOT_, and \$_NAND_, cells

G.7 alumacc - extract ALU and MACC cells

```
alumacc [selection]
```

This pass translates arithmetic operations like \$add, \$mul, \$lt, etc. to \$alu and \$macc cells.

G.8 anlogic_eqn - Anlogic: Calculate equations for luts

```
anlogic_eqn [selection]
```

Calculate equations for luts since bitstream generator depends on it.

G.9 anlogic_fixcarry - Anlogic: fix carry chain

```
anlogic_fixcarry [options] [selection]
```

Add Anlogic adders to fix carry chain if needed.

G.10 assertpmux - adds asserts for parallel muxes

```
assertpmux [options] [selection]
```

This command adds asserts to the design that assert that all parallel muxes (\$pmux cells) have a maximum of one of their inputs enable at any time.

-noinit

do not enforce the pmux condition during the init state

-always

usually the \$pmux condition is only checked when the \$pmux output is used by the mux tree it drives. this option will deactivate this additional constraint and check the \$pmux condition always.

G.11 async2sync - convert async FF inputs to sync circuits

```
async2sync [options] [selection]
```

This command replaces async FF inputs with sync circuits emulating the same behavior for when the async signals are actually synchronized to the clock.

This pass assumes negative hold time for the async FF inputs. For example when a reset deasserts with the clock edge, then the FF output will still drive the

(continues on next page)

(continued from previous page)

reset value in the next cycle regardless of the data-in value at the time of the clock edge.

G.12 attrmap - renaming attributes

```
attrmap [options] [selection]
```

This command renames attributes and/or maps key/value pairs to other key/value pairs.

```
-tocase <name>
    Match attribute names case-insensitively and set it to the specified
    name.

-rename <old_name> <new_name>
    Rename attributes as specified

-map <old_name>=<old_value> <new_name>=<new_value>
    Map key/value pairs as indicated.

-imap <old_name>=<old_value> <new_name>=<new_value>
    Like -map, but use case-insensitive match for <old_value> when
    it is a string value.

-remove <name>=<value>
    Remove attributes matching this pattern.

-modattr
    Operate on module attributes instead of attributes on wires and cells.
```

For example, mapping Xilinx-style "keep" attributes to Yosys-style:

```
attrmap -tocase keep -imap keep="true" keep=1 \
        -imap keep="false" keep=0 -remove keep=0
```

G.13 attrmvcp - move or copy attributes from wires to driving cells

```
attrmvcp [options] [selection]
```

Move or copy attributes on wires to the cells driving them.

```
-copy
    By default, attributes are moved. This will only add
    the attribute to the cell, without removing it from
    the wire.

-purge
```

(continues on next page)

(continued from previous page)

If no selected cell consumes the attribute, then it is left on the wire by default. This option will cause the attribute to be removed from the wire, even if no selected cell takes it.

-driven

By default, attributes are moved to the cell driving the wire. With this option set it will be moved to the cell driven by the wire instead.

-attr <attrname>

Move or copy this attribute. This option can be used multiple times.

G.14 **autoname** - automatically assign names to objects

```
autoname [selection]
```

Assign auto-generated public names to objects with private names (the ones with `$-`prefix).

G.15 **blackbox** - convert modules into blackbox modules

```
blackbox [options] [selection]
```

Convert modules into blackbox modules (remove contents and set the blackbox module attribute).

G.16 **bmuxmap** - transform `$bmux` cells to trees of `$mux` cells

```
bmuxmap [selection]
```

This pass transforms `$bmux` cells to trees of `$mux` cells.

-pmux

transform to `$pmux` instead of `$mux` cells.

G.17 bugpoint - minimize testcases

```
bugpoint [options] [-script <filename> | -command "<command>"]
```

This command minimizes the current design that is known to crash Yosys with the given script into a smaller testcase. It does this by removing an arbitrary part of the design and recursively invokes a new Yosys process with this modified design and the same script, repeating these steps while it can find a smaller design that still causes a crash. Once this command finishes, it replaces the current design with the smallest testcase it was able to produce.

In order to save the reduced testcase you must write this out to a file with another command after `bugpoint` like `write_rtlil` or `write_verilog`.

```
-script <filename> | -command "<command>"
```

use this script file or command to crash Yosys. required.

```
-yosys <filename>
```

use this Yosys binary. if not specified, `yosys` is used.

```
-grep "<string>"
```

only consider crashes that place this string in the log file.

```
-fast
```

run `proc_clean; clean -purge` after each minimization step. converges faster, but produces larger testcases, and may fail to produce any testcase at all if the crash is related to dangling wires.

```
-clean
```

run `proc_clean; clean -purge` before checking testcase and after finishing. produces smaller and more useful testcases, but may fail to produce any testcase at all if the crash is related to dangling wires.

It is possible to constrain which parts of the design will be considered for removal. Unless one or more of the following options are specified, all parts will be considered.

```
-modules
```

try to remove modules. modules with a `(* bugpoint_keep *)` attribute will be skipped.

```
-ports
```

try to remove module ports. ports with a `(* bugpoint_keep *)` attribute will be skipped (useful for clocks, resets, etc.)

```
-cells
```

try to remove cells. cells with a `(* bugpoint_keep *)` attribute will be skipped.

```
-connections
```

try to reconnect ports to 'x'.

```
-processes
```

(continues on next page)

(continued from previous page)

```
try to remove processes. processes with a (* bugpoint_keep *) attribute
will be skipped.

-assigns
  try to remove process assigns from cases.

-updates
  try to remove process updates from syncs.

-runner "<prefix>"
  child process wrapping command, e.g., "timeout 30", or valgrind.
```

G.18 bwmuxmap - replace \$bwmux cells with equivalent logic

```
bwmuxmap [options] [selection]
```

This pass replaces \$bwmux cells with equivalent logic

G.19 cd - a shortcut for 'select -module <name>'

```
cd <modname>
```

This is just a shortcut for 'select -module <modname>'.

```
cd <cellname>
```

When no module with the specified name is found, but there is a cell with the specified name in the current module, then this is equivalent to 'cd <celltype>'.

```
cd ..
```

Remove trailing substrings that start with '.' in current module name until the name of a module in the current design is generated, then switch to that module. Otherwise clear the current selection.

```
cd
```

This is just a shortcut for 'select -clear'.

G.20 check - check for obvious problems in the design

```
check [options] [selection]
```

This pass identifies the following problems in the current design:

- combinatorial loops
- two or more conflicting drivers for one wire
- used wires that do not have a driver

Options:

```
-noinit
    also check for wires which have the 'init' attribute set

-initdrv
    also check for wires that have the 'init' attribute set and are not
    driven by an FF cell type

-mapped
    also check for internal cells that have not been mapped to cells of the
    target architecture

-allow-tbuf
    modify the -mapped behavior to still allow $_TBUF_ cells

-assert
    produce a runtime error if any problems are found in the current design
```

G.21 chformal - change formal constraints of the design

```
chformal [types] [mode] [options] [selection]
```

Make changes to the formal constraints of the design. The [types] options the type of constraint to operate on. If none of the following options are given, the command will operate on all constraint types:

```
-assert    $assert cells, representing assert(...) constraints
-assume    $assume cells, representing assume(...) constraints
-live      $live cells, representing assert(s_eventually ...)
-fair      $fair cells, representing assume(s_eventually ...)
-cover     $cover cells, representing cover() statements
```

Exactly one of the following modes must be specified:

```
-remove
    remove the cells and thus constraints from the design

-early
    bypass FFs that only delay the activation of a constraint
```

(continues on next page)

(continued from previous page)

```
-delay <N>
    delay activation of the constraint by <N> clock cycles

-skip <N>
    ignore activation of the constraint in the first <N> clock cycles

-coverenable
    add cover statements for the enable signals of the constraints

-assert2assume
-assume2assert
-live2fair
-fair2live
    change the roles of cells as indicated. these options can be combined
```

G.22 chparam - re-evaluate modules with new parameters

```
chparam [ -set name value ]... [selection]
```

Re-evaluate the selected modules with new parameters. String values must be passed in double quotes (").

```
chparam -list [selection]
```

List the available parameters of the selected modules.

G.23 chtype - change type of cells in the design

```
chtype [options] [selection]
```

Change the types of cells in the design.

```
-set <type>
    set the cell type to the given type

-map <old_type> <new_type>
    change cells types that match <old_type> to <new_type>
```

G.24 clean - remove unused cells and wires

```
clean [options] [selection]
```

This is identical to 'opt_clean', but less verbose.

When commands are separated using the ';' token, this command will be executed between the commands.

When commands are separated using the ';;;' token, this command will be executed in -purge mode between the commands.

G.25 clean_zerowidth - clean zero-width connections from the design

```
clean_zerowidth [selection]
```

Fixes the selected cells and processes to contain no zero-width connections. Depending on the cell type, this may be implemented by removing the connection, widening it to 1-bit, or removing the cell altogether.

G.26 clk2fflogic - convert clocked FFs to generic \$ff cells

```
clk2fflogic [options] [selection]
```

This command replaces clocked flip-flops with generic \$ff cells that use the implicit global clock. This is useful for formal verification of designs with multiple clocks.

This pass assumes negative hold time for the async FF inputs. For example when a reset deasserts with the clock edge, then the FF output will still drive the reset value in the next cycle regardless of the data-in value at the time of the clock edge.

G.27 clkbufmap - insert clock buffers on clock networks

```
clkbufmap [options] [selection]
```

Inserts clock buffers between nets connected to clock inputs and their drivers.

In the absence of any selection, all wires without the 'clkbuf_inhibit' attribute will be considered for clock buffer insertion.

Alternatively, to consider all wires without the 'buffer_type' attribute set to 'none' or 'bufr' one would specify:

```
'w:* a:buffer_type=none a:buffer_type=bufr %u %d'
as the selection.
```

(continues on next page)

(continued from previous page)

```
-buf <celltype> <portname_out>:<portname_in>
    Specifies the cell type to use for the clock buffers
    and its port names. The first port will be connected to
    the clock network sinks, and the second will be connected
    to the actual clock source.

-inpad <celltype> <portname_out>:<portname_in>
    If specified, a PAD cell of the given type is inserted on
    clock nets that are also top module's inputs (in addition
    to the clock buffer, if any).
```

At least one of -buf or -inpad should be specified.

G.28 connect - create or remove connections

```
connect [-nomap] [-nounset] -set <lhs-expr> <rhs-expr>
```

Create a connection. This is equivalent to adding the statement 'assign <lhs-expr> = <rhs-expr>;' to the Verilog input. Per default, all existing drivers for <lhs-expr> are unconnected. This can be overwritten by using the -nounset option.

```
connect [-nomap] -unset <expr>
```

Unconnect all existing drivers for the specified expression.

```
connect [-nomap] [-assert] -port <cell> <port> <expr>
```

Connect the specified cell port to the specified cell port.

Per default signal alias names are resolved and all signal names are mapped the the signal name of the primary driver. Using the -nomap option deactivates this behavior.

The connect command operates in one module only. Either only one module must be selected or an active module must be set using the 'cd' command.

The -assert option verifies that the connection already exists, instead of making it.

This command does not operate on module with processes.

G.29 connect_rpc - connect to RPC frontend

```
connect_rpc -exec <command> [args...]
connect_rpc -path <path>
```

Load modules using an out-of-process frontend.

```
-exec <command> [args...]
    run <command> with arguments [args...]. send requests on stdin, read
    responses from stdout.

-path <path>
    connect to Unix domain socket at <path>. (Unix)
    connect to bidirectional byte-type named pipe at <path>. (Windows)
```

A simple JSON-based, newline-delimited protocol is used for communicating with the frontend. Yosys requests data from the frontend by sending exactly 1 line of JSON. Frontend responds with data or error message by replying with exactly 1 line of JSON as well.

```
-> {"method": "modules"}
<- {"modules": ["<module-name>", ...]}
<- {"error": "<error-message>"}
    request for the list of modules that can be derived by this frontend.
    the 'hierarchy' command will call back into this frontend if a cell
    with type <module-name> is instantiated in the design.

-> {"method": "derive", "module": "<module-name>", "parameters": {
    "<param-name>": {"type": "[unsigned|signed|string|real]",
                    "value": "<param-value>"}, ...}}
<- {"frontend": "[rtlil|verilog|...]", "source": "<source>"}
<- {"error": "<error-message>"}
    request for the module <module-name> to be derived for a specific set of
    parameters. <param-name> starts with \ for named parameters, and with $
    for unnamed parameters, which are numbered starting at 1.<param-value>
    for integer parameters is always specified as a binary string of
    unlimited precision. the <source> returned by the frontend is
    hygienically parsed by a built-in Yosys <frontend>, allowing the RPC
    frontend to return any convenient representation of the module. the
    derived module is cached, so the response should be the same whenever the
    same set of parameters is provided.
```

G.30 connwrappers - match width of input-output port pairs

```
connwrappers [options] [selection]
```

Wrappers are used in coarse-grain synthesis to wrap cells with smaller ports in wrapper cells with a (larger) constant port size. I.e. the upper bits of the wrapper output are signed/unsigned bit extended. This command uses this knowledge to rewire the inputs of the driven cells to match the output of

(continues on next page)

(continued from previous page)

the driving cell.

```
-signed <cell_type> <port_name> <width_param>
-unsigned <cell_type> <port_name> <width_param>
    consider the specified signed/unsigned wrapper output

-port <cell_type> <port_name> <width_param> <sign_param>
    use the specified parameter to decide if signed or unsigned
```

The options `-signed`, `-unsigned`, and `-port` can be specified multiple times.

G.31 coolrunner2_fixup - insert necessary buffer cells for CoolRunner-II architecture

```
coolrunner2_fixup [options] [selection]
```

Insert necessary buffer cells for CoolRunner-II architecture.

G.32 coolrunner2_sop - break \$sop cells into ANDTERM/ORTERM cells

```
coolrunner2_sop [options] [selection]
```

Break \$sop cells into ANDTERM/ORTERM cells.

G.33 copy - copy modules in the design

```
copy old_name new_name
```

Copy the specified module. Note that selection patterns are not supported by this command.

G.34 cover - print code coverage counters

```
cover [options] [pattern]
```

Print the code coverage counters collected using the `cover()` macro in the Yosys C++ code. This is useful to figure out what parts of Yosys are utilized by a test bench.

```
-q
```

(continues on next page)

(continued from previous page)

Do not print output to the normal destination (console and/or log file)

`-o file`

Write output to this file, truncate if exists.

`-a file`

Write output to this file, append if exists.

`-d dir`

Write output to a newly created file in the specified directory.

When one or more pattern (shell wildcards) are specified, then only counters matching at least one pattern are printed.

It is also possible to instruct Yosys to print the coverage counters on program exit to a file using environment variables:

```
YOSYS_COVER_DIR="{dir-name}" yosys {args}
```

This will create a file (with an auto-generated name) in this directory and write the coverage counters to it.

```
YOSYS_COVER_FILE="{file-name}" yosys {args}
```

This will append the coverage counters to the specified file.

Hint: Use the following AWK command to consolidate Yosys coverage files:

```
gawk '{ p[$3] = $1; c[$3] += $2; } END { for (i in p)
  printf "%-60s %10d %s\n", p[i], c[i], i; }' {files} | sort -k3
```

Coverage counters are only available in Yosys for Linux.

G.35 cutpoint - adds formal cut points to the design

```
cutpoint [options] [selection]
```

This command adds formal cut points to the design.

`-undef`

set cutpoint nets to undef (x). the default behavior is to create a \$anyseq cell and drive the cutpoint net from that

G.36 debug - run command with debug log messages enabled

```
debug cmd
```

Execute the specified command with debug log messages enabled

G.37 delete - delete objects in the design

```
delete [selection]
```

Deletes the selected objects. This will also remove entire modules, if the whole module is selected.

```
delete {-input|-output|-port} [selection]
```

Does not delete any object but removes the input and/or output flag on the selected wires, thus 'deleting' module ports.

G.38 deminout - demote inout ports to input or output

```
deminout [options] [selection]
```

"Demote" inout ports to input or output ports, if possible.

G.39 demuxmap - transform \$demux cells to \$eq + \$mux cells

```
demuxmap [selection]
```

This pass transforms \$demux cells to a bunch of equality comparisons.

G.40 design - save, restore and reset current design

```
design -reset
```

Clear the current design.

```
design -save <name>
```

Save the current design under the given name.

(continues on next page)

(continued from previous page)

```
design -stash <name>
```

Save the current design under the given name and then clear the current design.

```
design -push
```

Push the current design to the stack and then clear the current design.

```
design -push-copy
```

Push the current design to the stack without clearing the current design.

```
design -pop
```

Reset the current design and pop the last design from the stack.

```
design -load <name>
```

Reset the current design and load the design previously saved under the given name.

```
design -copy-from <name> [-as <new_mod_name>] <selection>
```

Copy modules from the specified design into the current one. The selection is evaluated in the other design.

```
design -copy-to <name> [-as <new_mod_name>] [selection]
```

Copy modules from the current design into the specified one.

```
design -import <name> [-as <new_top_name>] [selection]
```

Import the specified design into the current design. The source design must either have a selected top module or the selection must contain exactly one module that is then used as top module for this command.

```
design -reset-vlog
```

The Verilog front-end remembers defined macros and top-level declarations between calls to 'read_verilog'. This command resets this memory.

```
design -delete <name>
```

Delete the design previously saved under the given name.

G.41 dffinit - set INIT param on FF cells

```
dffinit [options] [selection]
```

This pass sets an FF cell parameter to the the initial value of the net it drives. (This is primarily used in FPGA flows.)

```
-ff <cell_name> <output_port> <init_param>
    operate on the specified cell type. this option can be used
    multiple times.

-highlow
    use the string values "high" and "low" to represent a single-bit
    initial value of 1 or 0. (multi-bit values are not supported in this
    mode.)

-strinit <string for high> <string for low>
    use string values in the command line to represent a single-bit
    initial value of 1 or 0. (multi-bit values are not supported in this
    mode.)

-noreinit
    fail if the FF cell has already a defined initial value set in other
    passes and the initial value of the net it drives is not equal to
    the already defined initial value.
```

G.42 dfflegalize - convert FFs to types supported by the target

```
dfflegalize [options] [selection]
```

Converts FFs to types supported by the target.

```
-cell <cell_type_pattern> <init_values>
    specifies a supported group of FF cells. <cell_type_pattern>
    is a yosys internal fine cell name, where ? characters can be
    as a wildcard matching any character. <init_values> specifies
    which initialization values these FF cells can support, and can
    be one of:

    - x (no init value supported)
    - 0
    - 1
    - r (init value has to match reset value, only for some FF types)
    - 01 (both 0 and 1 supported).

-mince <num>
    specifies a minimum number of FFs that should be using any given
    clock enable signal. If a clock enable signal doesn't meet this
    threshold, it is unmapped into soft logic.
```

(continues on next page)

(continued from previous page)

```
-minsrst <num>
    specifies a minimum number of FFs that should be using any given
    sync set/reset signal. If a sync set/reset signal doesn't meet this
    threshold, it is unmapped into soft logic.
```

The following cells are supported by this pass (ie. will be ingested, and can be specified as allowed targets):

```
- $_DFF_[NP]_
- $_DFFE_[NP][NP]_
- $_DFF_[NP][NP][01]_
- $_DFFE_[NP][NP][01][NP]_
- $_ALDFF_[NP][NP]_
- $_ALDFFE_[NP][NP][NP]_
- $_DFFSR_[NP][NP][NP]_
- $_DFFSRE_[NP][NP][NP][NP]_
- $_SDFF_[NP][NP][01]_
- $_SDFFE_[NP][NP][01][NP]_
- $_SDFFCE_[NP][NP][01][NP]_
- $_SR_[NP][NP]_
- $_DLATCH_[NP]_
- $_DLATCH_[NP][NP][01]_
- $_DLATCHSR_[NP][NP][NP]_
```

The following transformations are performed by this pass:

- upconversion from a less capable cell to a more capable cell, if the less capable cell is not supported (eg. dff -> dffe, or adff -> dffsr)
- unmapping FFs with clock enable (due to unsupported cell type or -mince)
- unmapping FFs with sync reset (due to unsupported cell type or -minsrst)
- adding inverters on the control pins (due to unsupported polarity)
- adding inverters on the D and Q pins and inverting the init/reset values (due to unsupported init or reset value)
- converting sr into adlatch (by tying D to 1 and using E as set input)
- emulating unsupported dffsr cell by adff + adff + sr + mux
- emulating unsupported dlatchsr cell by adlatch + adlatch + sr + mux
- emulating adff when the (reset, init) value combination is unsupported by dff + adff + dlatch + mux
- emulating adlatch when the (reset, init) value combination is unsupported by dlatch + adlatch + dlatch + mux

If the pass is unable to realize a given cell type (eg. adff when only plain dff is available), an error is raised.

G.43 dfflibmap - technology mapping of flip-flops

```
dfflibmap [-prepare] [-map-only] [-info] -liberty <file> [selection]
```

Map internal flip-flop cells to the flip-flop cells in the technology library specified in the given liberty file.

This pass may add inverters as needed. Therefore it is recommended to first run this pass and then map the logic paths to the target technology.

When called with `-prepare`, this command will convert the internal FF cells to the internal cell types that best match the cells found in the given liberty file, but won't actually map them to the target cells.

When called with `-map-only`, this command will only map internal cell types that are already of exactly the right type to match the target cells, leaving remaining internal cells untouched.

When called with `-info`, this command will only print the target cell list, along with their associated internal cell types, and the arguments that would be passed to the `dfflegalize` pass. The design will not be changed.

G.44 dffunmap - unmap clock enable and synchronous reset from FFs

```
dffunmap [options] [selection]
```

This pass transforms FF types with clock enable and/or synchronous reset into their base type (with neither clock enable nor sync reset) by emulating the clock enable and synchronous reset with multiplexers on the cell input.

`-ce-only`

unmap only clock enables, leave synchronous resets alone.

`-srst-only`

unmap only synchronous resets, leave clock enables alone.

G.45 dump - print parts of the design in RTLIL format

```
dump [options] [selection]
```

Write the selected parts of the design to the console or specified file in RTLIL format.

`-m`

also dump the module headers, even if only parts of a single module is selected

(continues on next page)

(continued from previous page)

```
-n
    only dump the module headers if the entire module is selected

-o <filename>
    write to the specified file.

-a <filename>
    like -outfile but append instead of overwrite
```

G.46 echo - turning echoing back of commands on and off

```
echo on
```

Print all commands to log before executing them.

```
echo off
```

Do not print all commands to log before executing them. (default)

G.47 ecp5_gsr - ECP5: handle GSR

```
ecp5_gsr [options] [selection]
```

Trim active low async resets connected to GSR and resolve GSR parameter, if a GSR or SGSR primitive is used in the design.

If any cell has the GSR parameter set to "AUTO", this will be resolved to "ENABLED" if a GSR primitive is present and the (* nogsr *) attribute is not set, otherwise it will be resolved to "DISABLED".

G.48 edgetypes - list all types of edges in selection

```
edgetypes [options] [selection]
```

This command lists all unique types of 'edges' found in the selection. An 'edge' is a 4-tuple of source and sink cell type and port name.

G.49 efinix_fixcarry - Efinix: fix carry chain

```
efinix_fixcarry [options] [selection]
```

Add Efinix adders to fix carry chain if needed.

G.50 equiv_add - add a \$equiv cell

```
equiv_add [-try] gold_sig gate_sig
```

This command adds an \$equiv cell for the specified signals.

```
equiv_add [-try] -cell gold_cell gate_cell
```

This command adds \$equiv cells for the ports of the specified cells.

G.51 equiv_induct - proving \$equiv cells using temporal induction

```
equiv_induct [options] [selection]
```

Uses a version of temporal induction to prove \$equiv cells.

Only selected \$equiv cells are proven and only selected cells are used to perform the proof.

```
-undef  
    enable modelling of undef states
```

```
-seq <N>  
    the max. number of time steps to be considered (default = 4)
```

This command is very effective in proving complex sequential circuits, when the internal state of the circuit quickly propagates to \$equiv cells.

However, this command uses a weak definition of 'equivalence': This command proves that the two circuits will not diverge after they produce equal outputs (observable points via \$equiv) for at least <N> cycles (the <N> specified via -seq).

Combined with simulation this is very powerful because simulation can give you confidence that the circuits start out synced for at least <N> cycles after reset.

G.52 equiv_make - prepare a circuit for equivalence checking

```
equiv_make [options] gold_module gate_module equiv_module
```

This creates a module annotated with \$equiv cells from two presumably equivalent modules. Use commands such as 'equiv_simple' and 'equiv_status' to work with the created equivalent checking module.

-inames

Also match cells and wires with \$... names.

-blacklist <file>

Do not match cells or signals that match the names in the file.

-encfile <file>

Match FSM encodings using the description from the file.

See 'help fsm_recode' for details.

-make_assert

Check equivalence with \$assert cells instead of \$equiv.

\$eqx (==) is used to compare signals.

Note: The circuit created by this command is not a miter (with something like a trigger output), but instead uses \$equiv cells to encode the equivalence checking problem. Use 'miter -equiv' if you want to create a miter circuit.

G.53 equiv_mark - mark equivalence checking regions

```
equiv_mark [options] [selection]
```

This command marks the regions in an equivalence checking module. Region 0 is the proven part of the circuit. Regions with higher numbers are connected unproven subcircuits. The integer attribute 'equiv_region' is set on all wires and cells.

G.54 equiv_miter - extract miter from equiv circuit

```
equiv_miter [options] miter_module [selection]
```

This creates a miter module for further analysis of the selected \$equiv cells.

-trigger

Create a trigger output

-cmp

Create cmp_* outputs for individual unproven \$equiv cells

-assert

Create a \$assert cell for each unproven \$equiv cell

(continues on next page)

(continued from previous page)

```
-undef
    Create compare logic that handles undefs correctly
```

G.55 equiv_opt - prove equivalence for optimized circuit

```
equiv_opt [options] [command]
```

This command uses temporal induction to check circuit equivalence before and after an optimization pass.

```
-run <from_label>:<to_label>
    only run the commands between the labels (see below). an empty
    from label is synonymous to the start of the command list, and empty to
    label is synonymous to the end of the command list.

-map <filename>
    expand the modules in this file before proving equivalence. this is
    useful for handling architecture-specific primitives.

-blacklist <file>
    Do not match cells or signals that match the names in the file
    (passed to equiv_make).

-assert
    produce an error if the circuits are not equivalent.

-multiclock
    run clk2fflogic before equivalence checking.

-async2sync
    run async2sync before equivalence checking.

-undef
    enable modelling of undef states during equiv_induct.

-nocheck
    disable running check before and after the command under test.
```

The following commands are executed by this verification command:

```
run_pass:
    hierarchy -auto-top
    design -save preopt
    check -assert    (unless -nocheck)
    [command]
    check -assert    (unless -nocheck)
    design -stash postopt
```

(continues on next page)

(continued from previous page)

```

prepare:
    design -copy-from preopt -as gold A:top
    design -copy-from postopt -as gate A:top

techmap:    (only with -map)
    techmap -wb -D EQUIV -autoproc -map <filename> ...

prove:
    clk2fflogic    (only with -multiclock)
    async2sync     (only with -async2sync)
    equiv_make -blacklist <filename> ... gold gate equiv
    equiv_induct [-undef] equiv
    equiv_status [-assert] equiv

restore:
    design -load preopt

```

G.56 equiv_purge - purge equivalence checking module

```
equiv_purge [options] [selection]
```

This command removes the proven part of an equivalence checking module, leaving only the unproven segments in the design. This will also remove and add module ports as needed.

G.57 equiv_remove - remove \$equiv cells

```
equiv_remove [options] [selection]
```

This command removes the selected \$equiv cells. If neither -gold nor -gate is used then only proven cells are removed.

```

-gold
    keep gold circuit

-gate
    keep gate circuit

```

G.58 equiv_simple - try proving simple \$equiv instances

```
equiv_simple [options] [selection]
```

This command tries to prove \$equiv cells using a simple direct SAT approach.

```
-v
    verbose output

-undef
    enable modelling of undef states

-short
    create shorter input cones that stop at shared nodes. This yields
    simpler SAT problems but sometimes fails to prove equivalence.

-nogroup
    disabling grouping of $equiv cells by output wire

-seq <N>
    the max. number of time steps to be considered (default = 1)
```

G.59 equiv_status - print status of equivalent checking module

```
equiv_status [options] [selection]
```

This command prints status information for all selected \$equiv cells.

```
-assert
    produce an error if any unproven $equiv cell is found
```

G.60 equiv_struct - structural equivalence checking

```
equiv_struct [options] [selection]
```

This command adds additional \$equiv cells based on the assumption that the gold and gate circuit are structurally equivalent. Note that this can introduce bad \$equiv cells in cases where the netlists are not structurally equivalent, for example when analyzing circuits with cells with commutative inputs. This command will also de-duplicate gates.

```
-fwd
    by default this command performs forward sweeps until nothing can
    be merged by forwards sweeps, then backward sweeps until forward
    sweeps are effective again. with this option set only forward sweeps
    are performed.

-fwonly <cell_type>
```

(continues on next page)

(continued from previous page)

add the specified cell type to the list of cell types that are only merged in forward sweeps and never in backward sweeps. \$equiv is in this list automatically.

`-icells`

by default, the internal RTL and gate cell types are ignored. add this option to also process those cell types with this command.

`-maxiter <N>`

maximum number of iterations to run before aborting

G.61 eval - evaluate the circuit given an input

```
eval [options] [selection]
```

This command evaluates the value of a signal given the value of all required inputs.

`-set <signal> <value>`

set the specified signal to the specified value.

`-set-undef`

set all unspecified source signals to undef (x)

`-table <signal>`

create a truth table using the specified input signals

`-show <signal>`

show the value for the specified signal. if no `-show` option is passed then all output ports of the current module are used.

G.62 exec - execute commands in the operating system shell

```
exec [options] -- [command]
```

Execute a command in the operating system shell. All supplied arguments are concatenated and passed as a command to `popen(3)`. Whitespace is not guaranteed to be preserved, even if quoted. `stdin` and `stderr` are not connected, while `stdout` is logged unless the `"-q"` option is specified.

`-q`

Suppress `stdout` and `stderr` from subprocess

`-expect-return <int>`

Generate an error if `popen()` does not return specified value.

May only be specified once; the final specified value is controlling

(continues on next page)

(continued from previous page)

```
if specified multiple times.
```

```
-expect-stdout <regex>  
  Generate an error if the specified regex does not match any line  
  in subprocess's stdout. May be specified multiple times.
```

```
-not-expect-stdout <regex>  
  Generate an error if the specified regex matches any line  
  in subprocess's stdout. May be specified multiple times.
```

```
Example: exec -q -expect-return 0 -- echo "bananapie" | grep "nana"
```

G.63 expose - convert internal signals to module ports

```
expose [options] [selection]
```

This command exposes all selected internal signals of a module as additional outputs.

```
-dff  
  only consider wires that are directly driven by register cell.
```

```
-cut  
  when exposing a wire, create an input/output pair and cut the internal  
  signal path at that wire.
```

```
-input  
  when exposing a wire, create an input port and disconnect the internal  
  driver.
```

```
-shared  
  only expose those signals that are shared among the selected modules.  
  this is useful for preparing modules for equivalence checking.
```

```
-evert  
  also turn connections to instances of other modules to additional  
  inputs and outputs and remove the module instances.
```

```
-evert-dff  
  turn flip-flops to sets of inputs and outputs.
```

```
-sep <separator>  
  when creating new wire/port names, the original object name is suffixed  
  with this separator (default: '.') and the port name or a type  
  designator for the exposed signal.
```

G.64 extract - find subcircuits and replace them with cells

```
extract -map <map_file> [options] [selection]
extract -mine <out_file> [options] [selection]
```

This pass looks for subcircuits that are isomorphic to any of the modules in the given map file and replaces them with instances of this modules. The map file can be a Verilog source file (*.v) or an RTLIL source file (*.il).

```
-map <map_file>
    use the modules in this file as reference. This option can be used
    multiple times.

-map %<design-name>
    use the modules in this in-memory design as reference. This option can
    be used multiple times.

-verbose
    print debug output while analyzing

-constports
    also find instances with constant drivers. this may be much
    slower than the normal operation.

-nodefaultswaps
    normally builtin port swapping rules for internal cells are used per
    default. This turns that off, so e.g. 'a^b' does not match 'b^a'
    when this option is used.

-compat <needle_type> <haystack_type>
    Per default, the cells in the map file (needle) must have the
    type as the cells in the active design (haystack). This option
    can be used to register additional pairs of types that should
    match. This option can be used multiple times.

-swap <needle_type> <port1>,<port2>[,...]
    Register a set of swappable ports for a needle cell type.
    This option can be used multiple times.

-perm <needle_type> <port1>,<port2>[,...] <portA>,<portB>[,...]
    Register a valid permutation of swappable ports for a needle
    cell type. This option can be used multiple times.

-cell_attr <attribute_name>
    Attributes on cells with the given name must match.

-wire_attr <attribute_name>
    Attributes on wires with the given name must match.

-ignore_parameters
    Do not use parameters when matching cells.
```

(continues on next page)

(continued from previous page)

```
-ignore_param <cell_type> <parameter_name>
    Do not use this parameter when matching cells.
```

This pass does not operate on modules with unprocessed processes in it.
(I.e. the 'proc' pass should be used first to convert processes to netlists.)

This pass can also be used for mining for frequent subcircuits. In this mode the following options are to be used instead of the -map option.

```
-mine <out_file>
    mine for frequent subcircuits and write them to the given RTLIL file

-mine_cells_span <min> <max>
    only mine for subcircuits with the specified number of cells
    default value: 3 5

-mine_min_freq <num>
    only mine for subcircuits with at least the specified number of matches
    default value: 10

-mine_limit_matches_per_module <num>
    when calculating the number of matches for a subcircuit, don't count
    more than the specified number of matches per module

-mine_max_fanout <num>
    don't consider internal signals with more than <num> connections
```

The modules in the map file may have the attribute 'extract_order' set to an integer value. Then this value is used to determine the order in which the pass tries to map the modules to the design (ascending, default value is 0).

See 'help techmap' for a pass that does the opposite thing.

G.65 extract_counter - Extract GreenPak4 counter cells

```
extract_counter [options] [selection]
```

This pass converts non-resettable or async resettable counters to counter cells. Use a target-specific 'techmap' map file to convert those cells to the actual target cells.

```
-maxwidth N
    Only extract counters up to N bits wide (default 64)

-minwidth N
    Only extract counters at least N bits wide (default 2)

-allow_arst yes|no
    Allow counters to have async reset (default yes)
```

(continues on next page)

(continued from previous page)

```
-dir up|down|both
    Look for up-counters, down-counters, or both (default down)

-pout X,Y,...
    Only allow parallel output from the counter to the listed cell types
    (if not specified, parallel outputs are not restricted)
```

G.66 extract_fa - find and extract full/half adders

```
extract_fa [options] [selection]
```

This pass extracts full/half adders from a gate-level design.

```
-fa, -ha
    Enable cell types (fa=full adder, ha=half adder)
    All types are enabled if none of this options is used

-d <int>
    Set maximum depth for extracted logic cones (default=20)

-b <int>
    Set maximum breadth for extracted logic cones (default=6)

-v
    Verbose output
```

G.67 extract_reduce - converts gate chains into \$reduce_* cells

```
extract_reduce [options] [selection]
```

converts gate chains into \$reduce_* cells

This command finds chains of \$AND_, \$OR_, and \$XOR_ cells and replaces them with their corresponding \$reduce_* cells. Because this command only operates on these cell types, it is recommended to map the design to only these cell types using the `abc -g` command. Note that, in some cases, it may be more effective to map the design to only \$AND_ cells, run extract_reduce, map the remaining parts of the design to AND/OR/XOR cells, and run extract_reduce a second time.

```
-allow-off-chain
    Allows matching of cells that have loads outside the chain. These cells
    will be replicated and folded into the $reduce_* cell, but the original
    cell will remain, driving its original loads.
```

G.68 extractinv - extract explicit inverter cells for invertible cell pins

```
extractinv [options] [selection]
```

Searches the design for all cells with invertible pins controlled by a cell parameter (eg. IS_CLK_INVERTED on many Xilinx cells) and removes the parameter. If the parameter was set to 1, inserts an explicit inverter cell in front of the pin instead. Normally used for output to ISE, which does not support the inversion parameters.

To mark a cell port as invertible, use (* invertible_pin = "param_name" *) on the wire in the blackbox module. The parameter value should have the same width as the port, and will be effectively XORed with it.

```
-inv <celltype> <portname_out>:<portname_in>
    Specifies the cell type to use for the inverters and its port names.
    This option is required.
```

G.69 flatten - flatten design

```
flatten [options] [selection]
```

This pass flattens the design by replacing cells by their implementation. This pass is very similar to the 'techmap' pass. The only difference is that this pass is using the current design as mapping library.

Cells and/or modules with the 'keep_hierarchy' attribute set will not be flattened by this command.

```
-wb
    Ignore the 'whitebox' attribute on cell implementations.
```

G.70 flowmap - pack LUTs with FlowMap

```
flowmap [options] [selection]
```

This pass uses the FlowMap technology mapping algorithm to pack logic gates into k-LUTs with optimal depth. It allows mapping any circuit elements that can be evaluated with the 'eval' pass, including cells with multiple output ports and multi-bit input and output ports.

```
-maxlut k
    perform technology mapping for a k-LUT architecture. if not specified,
    defaults to 3.

-minlut n
    only produce n-input or larger LUTs. if not specified, defaults to 1.
```

(continues on next page)

(continued from previous page)

```

-cells <cell>[,<cell>,...]
    map specified cells. if not specified, maps $_NOT_, $_AND_, $_OR_,
    $_XOR_ and $_MUX_, which are the outputs of the `simplemap` pass.

-relax
    perform depth relaxation and area minimization.

-r-alpha n, -r-beta n, -r-gamma n
    parameters of depth relaxation heuristic potential function.
    if not specified, alpha=8, beta=2, gamma=1.

-optarea n
    optimize for area by trading off at most n logic levels for fewer LUTs.
    n may be zero, to optimize for area without increasing depth.
    implies -relax.

-debug
    dump intermediate graphs.

-debug-relax
    explain decisions performed during depth relaxation.

```

G.71 fmcombine - combine two instances of a cell into one

```
fmcombine [options] module_name gold_cell gate_cell
```

This pass takes two cells, which are instances of the same module, and replaces them with one instance of a special 'combined' module, that effectively contains two copies of the original module, plus some formal properties.

This is useful for formal test benches that check what differences in behavior a slight difference in input causes in a module.

```

-initeq
    Insert assumptions that initially all FFs in both circuits have the
    same initial values.

-anyeq
    Do not duplicate $anyseq/$anyconst cells.

-fwd
    Insert forward hint assumptions into the combined module.

-bwd
    Insert backward hint assumptions into the combined module.
    (Backward hints are logically equivalent to forward hints, but
    some solvers are faster with bwd hints, or even both -bwd and -fwd.)

-nop

```

(continues on next page)

(continued from previous page)

Don't insert hint assumptions into the combined module.
 (This should not provide any speedup over the original design, but
 strangely sometimes it does.)

If none of -fwd, -bwd, and -nop is given, then -fwd is used as default.

G.72 fminit - set init values/sequences for formal

```
fminit [options] <selection>
```

This pass creates init constraints (for example for reset sequences) in a formal model.

```
-seq <signal> <sequence>
    Set sequence using comma-separated list of values, use 'z' for
    unconstrained bits. The last value is used for the remainder of the
    trace.

-set <signal> <value>
    Add constant value constraint

-posedge <signal>
-negedge <signal>
    Set clock for init sequences
```

G.73 formalff - prepare FFs for formal

```
formalff [options] [selection]
```

This pass transforms clocked flip-flops to prepare a design for formal verification. If a design contains latches and/or multiple different clocks run the async2sync or clk2fflogic passes before using this pass.

```
-clk2ff
    Replace all clocked flip-flops with $ff cells that use the implicit
    global clock. This assumes, without checking, that the design uses a
    single global clock. If that is not the case, the clk2fflogic pass
    should be used instead.

-ff2anyinit
    Replace uninitialized bits of $ff cells with $anyinit cells. An
    $anyinit cell behaves exactly like an $ff cell with an undefined
    initialization value. The difference is that $anyinit inhibits
    don't-care optimizations and is used to track solver-provided values
    in witness traces.

    If combined with -clk2ff this also affects newly created $ff cells.
```

(continues on next page)

(continued from previous page)

-anyinit2ff

Replaces \$anyinit cells with uninitialized \$ff cells. This performs the reverse of -ff2anyinit and can be used, before running a backend pass (or similar) that is not yet aware of \$anyinit cells.

Note that after running -anyinit2ff, in general, performing don't-care optimizations is not sound in a formal verification setting.

-fine

Emit fine-grained \$_FF_ cells instead of coarse-grained \$ff cells for -anyinit2ff. Cannot be combined with -clk2ff or -ff2anyinit.

-setundef

Find FFs with undefined initialization values for which changing the initialization does not change the observable behavior and initialize them. For -ff2anyinit, this reduces the number of generated \$anyinit cells that drive wires with private names.

-hierarchy

Propagates the 'replaced_by_gclk' attribute set by clk2ff upwards through the design hierarchy towards the toplevel inputs. This option works on the whole design and ignores the selection.

-assume

Add assumptions that constrain wires with the 'replaced_by_gclk' attribute to the value they would have before an active clock edge.

G.74 freduce - perform functional reduction

```
freduce [options] [selection]
```

This pass performs functional reduction in the circuit. I.e. if two nodes are equivalent, they are merged to one node and one of the redundant drivers is disconnected. A subsequent call to 'clean' will remove the redundant drivers.

-v, -vv

enable verbose or very verbose output

-inv

enable explicit handling of inverted signals

-stop <n>

stop after <n> reduction operations. this is mostly used for debugging the freduce command itself.

-dump <prefix>

dump the design to <prefix>_<module>_<num>.il after each reduction operation. this is mostly used for debugging the freduce command.

(continues on next page)

(continued from previous page)

This pass is undef-aware, i.e. it considers don't-care values for detecting equivalent nodes.

All selected wires are considered for rewiring. The selected cells cover the circuit that is analyzed.

G.75 fsm - extract and optimize finite state machines

```
fsm [options] [selection]
```

This pass calls all the other fsm_* passes in a useful order. This performs FSM extraction and optimization. It also calls opt_clean as needed:

```
fsm_detect          unless got option -nodetect
fsm_extract

fsm_opt
opt_clean
fsm_opt

fsm_expand          if got option -expand
opt_clean           if got option -expand
fsm_opt             if got option -expand

fsm_recode          unless got option -norecode

fsm_info

fsm_export          if got option -export
fsm_map             unless got option -nomap
```

Options:

```
-expand, -norecode, -export, -nomap
    enable or disable passes as indicated above

-fullexpand
    call expand with -full option

-encoding type
-fm_set_fsm_file file
-encfile file
    passed through to fsm_recode pass
```

This pass uses a subset of FF types to detect FSMs. Run 'opt -nosdff -nodffe' before this pass to prepare the design.

G.76 fsm_detect - finding FSMs in design

```
fsm_detect [options] [selection]
```

This pass detects finite state machines by identifying the state signal. The state signal is then marked by setting the attribute 'fsm_encoding' on the state signal to "auto".

```
-ignore-self-reset
    Mark FSMs even if they are self-resetting
```

Existing 'fsm_encoding' attributes are not changed by this pass.

Signals can be protected from being detected by this pass by setting the 'fsm_encoding' attribute to "none".

This pass uses a subset of FF types to detect FSMs. Run 'opt -nosdff -nodffe' before this pass to prepare the design for fsm_detect.

G.77 fsm_expand - expand FSM cells by merging logic into it

```
fsm_expand [-full] [selection]
```

The fsm_extract pass is conservative about the cells that belong to a finite state machine. This pass can be used to merge additional auxiliary gates into the finite state machine.

By default, fsm_expand is still a bit conservative regarding merging larger word-wide cells. Call with -full to consider all cells for merging.

G.78 fsm_export - exporting FSMs to KISS2 files

```
fsm_export [-noauto] [-o filename] [-origenc] [selection]
```

This pass creates a KISS2 file for every selected FSM. For FSMs with the 'fsm_export' attribute set, the attribute value is used as filename, otherwise the module and cell name is used as filename. If the parameter '-o' is given, the first exported FSM is written to the specified filename. This overwrites the setting as specified with the 'fsm_export' attribute. All other FSMs are exported to the default name as mentioned above.

```
-noauto
    only export FSMs that have the 'fsm_export' attribute set

-o filename
    filename of the first exported FSM
```

(continues on next page)

(continued from previous page)

```
-origenc
    use binary state encoding as state names instead of s0, s1, ...
```

G.79 fsm_extract - extracting FSMs in design

```
fsm_extract [selection]
```

This pass operates on all signals marked as FSM state signals using the 'fsm_encoding' attribute. It consumes the logic that creates the state signal and uses the state signal to generate control signal and replaces it with an FSM cell.

The generated FSM cell still generates the original state signal with its original encoding. The 'fsm_opt' pass can be used in combination with the 'opt_clean' pass to eliminate this signal.

G.80 fsm_info - print information on finite state machines

```
fsm_info [selection]
```

This pass dumps all internal information on FSM cells. It can be useful for analyzing the synthesis process and is called automatically by the 'fsm' pass so that this information is included in the synthesis log file.

G.81 fsm_map - mapping FSMs to basic logic

```
fsm_map [selection]
```

This pass translates FSM cells to flip-flops and logic.

G.82 fsm_opt - optimize finite state machines

```
fsm_opt [selection]
```

This pass optimizes FSM cells. It detects which output signals are actually not used and removes them from the FSM. This pass is usually used in combination with the 'opt_clean' pass (see also 'help fsm').

G.83 fsm_recode - recoding finite state machines

```
fsm_recode [options] [selection]
```

This pass reassign the state encodings for FSM cells. At the moment only one-hot encoding and binary encoding is supported.

```
-encoding <type>
    specify the encoding scheme used for FSMs without the
    'fsm_encoding' attribute or with the attribute set to `auto'.

-fm_set_fsm_file <file>
    generate a file containing the mapping from old to new FSM encoding
    in form of Synopsys Formality set_fsm_* commands.

-encfile <file>
    write the mappings from old to new FSM encoding to a file in the
    following format:

        .fsm <module_name> <state_signal>
        .map <old_bitpattern> <new_bitpattern>
```

G.84 fst2tb - generate testbench out of fst file

```
fst2tb [options] [top-level]
```

This command generates testbench for the circuit using the given top-level module and stimulus signal from FST file

```
-tb <name>
    generated testbench name.
    files <name>.v and <name>.txt are created as result.

-r <filename>
    read simulation FST file

-clock <portname>
    name of top-level clock input

-clockn <portname>
    name of top-level clock input (inverse polarity)

-scope <name>
    scope of simulation top model

-start <time>
    start co-simulation in arbitrary time (default 0)

-stop <time>
    stop co-simulation in arbitrary time (default END)
```

(continues on next page)

(continued from previous page)

```
-n <integer>
    number of clock cycles to simulate (default: 20)
```

G.85 gatemate_foldinv - fold inverters into Gatemate LUT trees

```
gatemate_foldinv [selection]
```

This pass searches for `$_CC_NOT` cells and folds them into `CC_LUT2`, `CC_L2T4` and `CC_L2T5` cells as created by LUT tree mapping.

G.86 glift - create GLIFT models and optimization problems

```
glift <command> [options] [selection]
```

Augments the current or specified module with gate-level information flow tracking (GLIFT) logic using the "constructive mapping" approach. Also can set up QBF-SAT optimization problems in order to optimize GLIFT models or trade off precision and complexity.

Commands:

```
-create-precise-model
```

Replaces the current or specified module with one that has corresponding "taint" inputs, outputs, and internal nets along with precise taint tracking logic. For example, precise taint tracking logic for an AND gate is:

```
y_t = a & b_t | b & a_t | a_t & b_t
```

```
-create-imprecise-model
```

Replaces the current or specified module with one that has corresponding "taint" inputs, outputs, and internal nets along with imprecise "All OR" taint tracking logic:

```
y_t = a_t | b_t
```

```
-create-instrumented-model
```

Replaces the current or specified module with one that has corresponding "taint" inputs, outputs, and internal nets along with 4 varying-precision versions of taint tracking logic. Which version of taint tracking logic is used for a given gate is determined by a MUX selected by an `$anyconst` cell.

By default, unless the ``-no-cost-model`` option is provided, an additional wire named ``__glift_weight`` with the ``keep`` and ``minimize`` attributes is

(continues on next page)

(continued from previous page)

added to the module along with pmuxes and adders to calculate a rough estimate of the number of logic gates in the GLIFT model given an assignment for the \$anyconst cells. The four versions of taint tracking logic for an AND gate are:

```

y_t = a & b_t | b & a_t | a_t & b_t      (like `--create-precise-model`)
y_t = a_t | a & b_t
y_t = b_t | b & a_t
y_t = a_t | b_t                          (like `--create-imprecise-model`)

```

Options:

-taint-constants

Constant values in the design are labeled as tainted.
(default: label constants as un-tainted)

-keep-outputs

Do not remove module outputs. Taint tracking outputs will appear in the module ports alongside the original outputs.
(default: original module outputs are removed)

-simple-cost-model

Do not model logic area. Instead model the number of non-zero assignments to \$anyconsts. Taint tracking logic versions vary in their size, but all reduced-precision versions are significantly smaller than the fully-precise version. A non-zero \$anyconst assignment means that reduced-precision taint tracking logic was chosen for some gate. Only applicable in combination with `--create-instrumented-model`. (default: use a complex model and give that wire the "keep" and "minimize" attributes)

-no-cost-model

Do not model taint tracking logic area and do not create a `__glift_weight` wire. Only applicable in combination with `--create-instrumented-model`. (default: model area and give that wire the "keep" and "minimize" attributes)

-instrument-more

Allow choice from more versions of (even simpler) taint tracking logic. A total of 8 versions of taint tracking logic will be added per gate, including the 4 versions from `--create-instrumented-model` and these additional versions:

```

y_t = a_t
y_t = b_t
y_t = 1
y_t = 0

```

Only applicable in combination with `--create-instrumented-model`.
(default: do not add more versions of taint tracking logic.)

G.87 greenpak4_dffinv - merge greenpak4 inverters and DFF/latches

```
greenpak4_dffinv [options] [selection]
```

Merge GP_INV cells with GP_DFF* and GP_DLATCH* cells.

G.88 help - display help messages

```
help ..... list all commands
help <command> ..... print help message for given command
help -all ..... print complete command reference

help -cells ..... list all cell types
help <celltype> ..... print help message for given cell type
help <celltype>+ .... print verilog code for given cell type
```

G.89 hierarchy - check, expand and clean up design hierarchy

```
hierarchy [-check] [-top <module>]
hierarchy -generate <cell-types> <port-decls>
```

In parametric designs, a module might exist in several variations with different parameter values. This pass looks at all modules in the current design and re-runs the language frontends for the parametric modules as needed. It also resolves assignments to wired logic data types (wand/wor), resolves positional module parameters, unrolls array instances, and more.

```
-check
    also check the design hierarchy. this generates an error when
    an unknown module is used as cell type.

-simcheck
    like -check, but also throw an error if blackbox modules are
    instantiated, and throw an error if the design has no top module.

-smtcheck
    like -simcheck, but allow smtlib2_module modules.

-purge_lib
    by default the hierarchy command will not remove library (blackbox)
    modules. use this option to also remove unused blackbox modules.

-libdir <directory>
    search for files named <module_name>.v in the specified directory
    for unknown modules and automatically run read_verilog for each
    unknown module.

-keep_positionals
```

(continues on next page)

(continued from previous page)

per default this pass also converts positional arguments in cells to arguments using port names. This option disables this behavior.

-keep_portwidths

per default this pass adjusts the port width on cells that are module instances when the width does not match the module port. This option disables this behavior.

-nodefaults

do not resolve input port default values

-nokeep_asserts

per default this pass sets the "keep" attribute on all modules that directly or indirectly contain one or more formal properties. This option disables this behavior.

-top <module>

use the specified top module to build the design hierarchy. Modules outside this tree (unused modules) are removed.

when the -top option is used, the 'top' attribute will be set on the specified top module. otherwise a module with the 'top' attribute set will implicitly be used as top module, if such a module exists.

-auto-top

automatically determine the top of the design hierarchy and mark it.

-chparam name value

elaborate the top module using this parameter value. Modules on which this parameter does not exist may cause a warning message to be output. This option can be specified multiple times to override multiple parameters. String values must be passed in double quotes (").

In -generate mode this pass generates blackbox modules for the given cell types (wildcards supported). For this the design is searched for cells that match the given types and then the given port declarations are used to determine the direction of the ports. The syntax for a port declaration is:

```
{i|o|io}[@<num>]:<portname>
```

Input ports are specified with the 'i' prefix, output ports with the 'o' prefix and inout ports with the 'io' prefix. The optional <num> specifies the position of the port in the parameter list (needed when instantiated using positional arguments). When <num> is not specified, the <portname> can also contain wildcard characters.

This pass ignores the current selection and always operates on all modules in the current design.

G.90 hilomap - technology mapping of constant hi- and/or lo-drivers

```
hilomap [options] [selection]
```

Map constants to 'tielo' and 'tiehi' driver cells.

```
-hicell <celltype> <portname>  
    Replace constant hi bits with this cell.
```

```
-locell <celltype> <portname>  
    Replace constant lo bits with this cell.
```

```
-singleton  
    Create only one hi/lo cell and connect all constant bits  
    to that cell. Per default a separate cell is created for  
    each constant bit.
```

G.91 history - show last interactive commands

```
history
```

This command prints all commands in the shell history buffer. This are all commands executed in an interactive session, but not the commands from executed scripts.

G.92 ice40_braminit - iCE40: perform SB_RAM40_4K initialization from file

```
ice40_braminit
```

This command processes all SB_RAM40_4K blocks with a non-empty INIT_FILE parameter and converts it into the required INIT_x attributes

G.93 ice40_dsp - iCE40: map multipliers

```
ice40_dsp [options] [selection]
```

Map multipliers (\$mul/SB_MAC16) and multiply-accumulate (\$mul/SB_MAC16 + \$add) cells into iCE40 DSP resources.

Currently, only the 16x16 multiply mode is supported and not the 2 x 8x8 mode.

Pack input registers (A, B, {C,D}; with optional hold), pipeline registers ({F,J,K,G}, H), output registers (O -- full 32-bits or lower 16-bits only; with optional hold), and post-adder into into the SB_MAC16 resource.

(continues on next page)

(continued from previous page)

Multiply-accumulate operations using the post-adder with feedback on the {C,D} input will be folded into the DSP. In this scenario only, resetting the accumulator to an arbitrary value can be inferred to use the {C,D} input.

G.94 ice40_opt - iCE40: perform simple optimizations

```
ice40_opt [options] [selection]
```

This command executes the following script:

```
do
    <ice40 specific optimizations>
    opt_expr -mux_undef -undriven [-full]
    opt_merge
    opt_dff
    opt_clean
while <changed design>
```

G.95 ice40_wrapcarry - iCE40: wrap carries

```
ice40_wrapcarry [selection]
```

Wrap manually instantiated SB_CARRY cells, along with their associated SB_LUT4s, into an internal \$__ICE40_CARRY_WRAPPER cell for preservation across technology mapping.

Attributes on both cells will have their names prefixed with 'SB_CARRY.' or 'SB_LUT4.' and attached to the wrapping cell.

A (* keep *) attribute on either cell will be logically OR-ed together.

```
-unwrap
    unwrap $__ICE40_CARRY_WRAPPER cells back into SB_CARRYs and SB_LUT4s,
    including restoring their attributes.
```

G.96 insbuf - insert buffer cells for connected wires

```
insbuf [options] [selection]
```

Insert buffer cells into the design for directly connected wires.

```
-buf <celltype> <in-portname> <out-portname>
    Use the given cell type instead of $_BUF_. (Notice that the next
    call to "clean" will remove all $_BUF_ in the design.)
```

(continues on next page)

(continued from previous page)

```
-chain
    Chain buffer cells
```

G.97 iopadmap - technology mapping of i/o pads (or buffers)

```
iopadmap [options] [selection]
```

Map module inputs/outputs to PAD cells from a library. This pass can only map to very simple PAD cells. Use 'techmap' to further map the resulting cells to more sophisticated PAD cells.

```
-inpad <celltype> <in_port>[:<ext_port>]
    Map module input ports to the given cell type with the
    given output port name. if a 2nd portname is given, the
    signal is passed through the pad cell, using the 2nd
    portname as the port facing the module port.

-outpad <celltype> <out_port>[:<ext_port>]
-inoutpad <celltype> <io_port>[:<ext_port>]
    Similar to -inpad, but for output and inout ports.

-toutpad <celltype> <oe_port>:<out_port>[:<ext_port>]
    Merges $_TBUF_ cells into the output pad cell. This takes precedence
    over the other -outpad cell. The first portname is the enable input
    of the tristate driver, which can be prefixed with `~` for negative
    polarity enable.

-tinoutpad <celltype> <oe_port>:<in_port>:<out_port>[:<ext_port>]
    Merges $_TBUF_ cells into the inout pad cell. This takes precedence
    over the other -inoutpad cell. The first portname is the enable input
    of the tristate driver and the 2nd portname is the internal output
    buffering the external signal. Like with `-toutpad`, the enable can
    be marked as negative polarity by prefixing the name with `~`.

-ignore <celltype> <portname>[:<portname>]*
    Skips mapping inputs/outputs that are already connected to given
    ports of the given cell. Can be used multiple times. This is in
    addition to the cells specified as mapping targets.

-widthparam <param_name>
    Use the specified parameter name to set the port width.

-nameparam <param_name>
    Use the specified parameter to set the port name.

-bits
    create individual bit-wide buffers even for ports that
    are wider. (the default behavior is to create word-wide
    buffers using -widthparam to set the word size on the cell.)
```

(continues on next page)

(continued from previous page)

Tristate PADS (-toutpad, -tinoutpad) always operate in -bits mode.

G.98 jny - write design and metadata

```
jny [options] [selection]
```

Write JSON netlist metadata for the current design

```
-o <filename>
    write to the specified file.

-no-connections
    Don't include connection information in the netlist output.

-no-attributes
    Don't include attributed information in the netlist output.

-no-properties
    Don't include property information in the netlist output.
```

See 'help write_jny' for a description of the JSON format used.

G.99 json - write design in JSON format

```
json [options] [selection]
```

Write a JSON netlist of all selected objects.

```
-o <filename>
    write to the specified file.

-aig
    also include AIG models for the different gate types

-compat-int
    emit 32-bit or smaller fully-defined parameter values directly
    as JSON numbers (for compatibility with old parsers)
```

See 'help write_json' for a description of the JSON format used.

G.100 log - print text and log files

log string

Print the given string to the screen and/or the log file. This is useful for TCL scripts, because the TCL command "puts" only goes to stdout but not to logfiles.

-stdout

Print the output to stdout too. This is useful when all Yosys is executed with a script and the -q (quiet operation) argument to notify the user.

-stderr

Print the output to stderr too.

-nolog

Don't use the internal log() command. Use either -stdout or -stderr, otherwise no output will be generated at all.

-n

do not append a newline

G.101 logger - set logger properties

logger [options]

This command sets global logger properties, also available using command line options.

-[no]time

enable/disable display of timestamp in log output.

-[no]stderr

enable/disable logging errors to stderr.

-warn regex

print a warning for all log messages matching the regex.

-nowarn regex

if a warning message matches the regex, it is printed as regular message instead.

-werror regex

if a warning message matches the regex, it is printed as error message instead and the tool terminates with a nonzero return code.

-[no]debug

globally enable/disable debug log messages.

(continues on next page)

(continued from previous page)

```

-experimental <feature>
    do not print warnings for the specified experimental feature

-expect <type> <regex> <expected_count>
    expect log, warning or error to appear. matched errors will terminate
    with exit code 0.

-expect-no-warnings
    gives error in case there is at least one warning that is not expected.

-check-expected
    verifies that the patterns previously set up by -expect have actually
    been met, then clears the expected log list. If this is not called
    manually, the check will happen at yosys exist time instead.

```

G.102 ls - list modules or objects in modules

```
ls [selection]
```

When no active module is selected, this prints a list of modules.

When an active module is selected, this prints a list of objects in the module.

G.103 ltp - print longest topological path

```
ltp [options] [selection]
```

This command prints the longest topological path in the design. (Only considers paths within a single module, so the design must be flattened.)

```

-noff
    automatically exclude FF cell types

```

G.104 lut2mux - convert \$lut to \$_MUX_

```
lut2mux [options] [selection]
```

This pass converts \$lut cells to \$_MUX_ gates.

G.105 maccmap - mapping macc cells

```
maccmap [-unmap] [selection]
```

This pass maps \$macc cells to yosys \$fa and \$alu cells. When the -unmap option is used then the \$macc cell is mapped to \$add, \$sub, etc. cells instead.

G.106 memory - translate memories to basic cells

```
memory [-norom] [-nomap] [-nordff] [-nowiden] [-nosat] [-memx] [-no-rw-check] [-bram  
→<bram_rules>] [selection]
```

This pass calls all the other memory_* passes in a useful order:

```
opt_mem
opt_mem_priority
opt_mem_feedback
memory_bmux2rom                (skipped if called with -norom)
memory_dff [-no-rw-check]      (skipped if called with -nordff or -memx)
opt_clean
memory_share [-nowiden] [-nosat]
opt_mem_widen
memory_memx                    (when called with -memx)
opt_clean
memory_collect
memory_bram -rules <bram_rules> (when called with -bram)
memory_map                    (skipped if called with -nomap)
```

This converts memories to word-wide DFFs and address decoders or multiport memory blocks if called with the -nomap option.

G.107 memory_bmux2rom - convert muxes to ROMs

```
memory_bmux2rom [options] [selection]
```

This pass converts \$bmux cells with constant A input to ROMs.

G.108 memory_bram - map memories to block rams

```
memory_bram -rules <rule_file> [selection]
```

This pass converts the multi-port \$mem memory cells into block ram instances. The given rules file describes the available resources and how they should be used.

(continues on next page)

(continued from previous page)

The rules file contains configuration options, a set of block ram description and a sequence of match rules.

The option 'attr_icode' configures how attribute values are matched. The value 0 means case-sensitive, 1 means case-insensitive.

A block ram description looks like this:

```

    bram RAMB1024X32      # name of BRAM cell
      init 1              # set to '1' if BRAM can be initialized
      abits 10             # number of address bits
      dbits 32             # number of data bits
      groups 2            # number of port groups
      ports 1 1           # number of ports in each group
      wrmode 1 0          # set to '1' if this groups is write ports
      enable 4 1          # number of enable bits
      transp 0 2          # transparent (for read ports)
      clocks 1 2          # clock configuration
      clkpol 2 2          # clock polarity configuration
    endbram

```

For the option 'transp' the value 0 means non-transparent, 1 means transparent and a value greater than 1 means configurable. All groups with the same value greater than 1 share the same configuration bit.

For the option 'clocks' the value 0 means non-clocked, and a value greater than 0 means clocked. All groups with the same value share the same clock signal.

For the option 'clkpol' the value 0 means negative edge, 1 means positive edge and a value greater than 1 means configurable. All groups with the same value greater than 1 share the same configuration bit.

Using the same bram name in different bram blocks will create different variants of the bram. Verilog configuration parameters for the bram are created as needed.

It is also possible to create variants by repeating statements in the bram block and appending '@<label>' to the individual statements.

A match rule looks like this:

```

    match RAMB1024X32
      max waste 16384      # only use this bram if <= 16k ram bits are unused
      min efficiency 80    # only use this bram if efficiency is at least 80%
    endmatch

```

It is possible to match against the following values with min/max rules:

```

    words ..... number of words in memory in design
    abits ..... number of address bits on memory in design
    dbits ..... number of data bits on memory in design

```

(continues on next page)

(continued from previous page)

```

wports ..... number of write ports on memory in design
rports ..... number of read ports on memory in design
ports ..... number of ports on memory in design
bits ..... number of bits in memory in design
dups ..... number of duplications for more read ports

awaste ..... number of unused address slots for this match
dwaste ..... number of unused data bits for this match
bwaste ..... number of unused bram bits for this match
waste ..... total number of unused bram bits (bwaste*dups)
efficiency ... total percentage of used and non-duplicated bits

acells ..... number of cells in 'address-direction'
dcells ..... number of cells in 'data-direction'
cells ..... total number of cells (acells*dcells*dups)

```

A match containing the command 'attribute' followed by a list of space separated 'name[=string_value]' values requires that the memory contains any one of the given attribute name and string values (where specified), or name and integer 1 value (if no string_value given, since Verilog will interpret '(* attr *)' as '(* attr=1 *)').

A name prefixed with '!' indicates that the attribute must not exist.

The interface for the created bram instances is derived from the bram description. Use 'techmap' to convert the created bram instances into instances of the actual bram cells of your target architecture.

A match containing the command 'or_next_if_better' is only used if it has a higher efficiency than the next match (and the one after that if the next also has 'or_next_if_better' set, and so forth).

A match containing the command 'make_transp' will add external circuitry to simulate 'transparent read', if necessary.

A match containing the command 'make_outreg' will add external flip-flops to implement synchronous read ports, if necessary.

A match containing the command 'shuffle_enable A' will re-organize the data bits to accommodate the enable pattern of port A.

G.109 memory_collect - creating multi-port memory cells

```
memory_collect [selection]
```

This pass collects memories and memory ports and creates generic multiport memory cells.

G.110 memory_dff - merge input/output DFFs into memory read ports

```
memory_dff [-no-rw-check] [selection]
```

This pass detects DFFs at memory read ports and merges them into the memory port. I.e. it consumes an asynchronous memory port and the flip-flops at its interface and yields a synchronous memory port.

```
-no-rw-check
```

marks all recognized read ports as "return don't-care value on read/write collision" (same result as setting the `no_rw_check` attribute on all memories).

G.111 memory_libmap - map memories to cells

```
memory_libmap -lib <library_file> [-D <condition>] [selection]
```

This pass takes a description of available RAM cell types and maps all selected memories to one of them, or leaves them to be mapped to FFs.

```
-lib <library_file>
```

Selects a library file containing RAM cell definitions. This option can be passed more than once to select multiple libraries. See `passes/memory/memlib.md` for description of the library format.

```
-D <condition>
```

Enables a condition that can be checked within the library file to eg. select between slightly different hardware variants. This option can be passed any number of times.

```
-logic-cost-rom <num>
```

```
-logic-cost-ram <num>
```

Sets the cost of a single bit for memory lowered to soft logic.

```
-no-auto-distributed
```

```
-no-auto-block
```

```
-no-auto-huge
```

Disables automatic mapping of given kind of RAMs. Manual mapping (using `ram_style` or other attributes) is still supported.

G.112 memory_map - translate multiport memories to basic cells

```
memory_map [options] [selection]
```

This pass converts multiport memory cells as generated by the memory_collect pass to word-wide DFFs and address decoders.

```
-attr !<name>
    do not map memories that have attribute <name> set.

-attr <name>[=<value>]
    for memories that have attribute <name> set, only map them if its value
    is a string <value> (if specified), or an integer 1 (otherwise). if this
    option is specified multiple times, map the memory if the attribute is
    to any of the values.

-iattr
    for -attr, ignore case of <value>.

-rom-only
    only perform conversion for ROMs (memories with no write ports).

-keepdc
    when mapping ROMs, keep x-bits shared across read ports.

-formal
    map memories for a global clock based formal verification flow.
    This implies -keepdc, uses $ff cells for ROMs and sets hdlname
    attributes. It also has limited support for async write ports
    as generated by clk2fflogic.
```

G.113 memory_memx - emulate vlog sim behavior for mem ports

```
memory_memx [selection]
```

This pass adds additional circuitry that emulates the Verilog simulation behavior for out-of-bounds memory reads and writes.

G.114 memory_narrow - split up wide memory ports

```
memory_narrow [options] [selection]
```

This pass splits up wide memory ports into several narrow ports.

G.115 memory_nordff - extract read port FFs from memories

```
memory_nordff [options] [selection]
```

This pass extracts FFs from memory read ports. This results in a netlist similar to what one would get from not calling memory_dff.

G.116 memory_share - consolidate memory ports

```
memory_share [-nosat] [-nowiden] [selection]
```

This pass merges share-able memory ports into single memory ports.

The following methods are used to consolidate the number of memory ports:

- When multiple write ports access the same address then this is converted to a single write port with a more complex data and/or enable logic path.
- When multiple read or write ports access adjacent aligned addresses, they are merged to a single wide read or write port. This transformation can be disabled with the "-nowiden" option.
- When multiple write ports are never accessed at the same time (a SAT solver is used to determine this), then the ports are merged into a single write port. This transformation can be disabled with the "-nosat" option.

Note that in addition to the algorithms implemented in this pass, the \$memrd and \$memwr cells are also subject to generic resource sharing passes (and other optimizations) such as "share" and "opt_merge".

G.117 memory_unpack - unpack multi-port memory cells

```
memory_unpack [selection]
```

This pass converts the multi-port \$mem memory cells into individual \$memrd and \$memwr cells. It is the counterpart to the memory_collect pass.

G.118 miter - automatically create a miter circuit

```
miter -equiv [options] gold_name gate_name miter_name
```

Creates a miter circuit for equivalence checking. The gold- and gate- modules must have the same interfaces. The miter circuit will have all inputs of the two source modules, prefixed with 'in_'. The miter circuit has a 'trigger' output that goes high if an output mismatch between the two source modules is

(continues on next page)

(continued from previous page)

detected.

- ignore_gold_x
 - a undef (x) bit in the gold module output will match any value in the gate module output.
- make_outputs
 - also route the gold- and gate-outputs to 'gold_*' and 'gate_*' outputs on the miter circuit.
- make_outcmp
 - also create a cmp_* output for each gold/gate output pair.
- make_assert
 - also create an 'assert' cell that checks if trigger is always low.
- make_cover
 - also create a 'cover' cell for each gold/gate output pair.
- flatten
 - call 'flatten -wb; opt_expr -keepdc -undriven;;' on the miter circuit.
- cross
 - allow output ports on the gold module to match input ports on the gate module. This is useful when the gold module contains additional logic to drive some of the gate module inputs.

miter -assert [options] module [miter_name]

Creates a miter circuit for property checking. All input ports are kept, output ports are discarded. An additional output 'trigger' is created that goes high when an assert is violated. Without a miter_name, the existing module is modified.

- make_outputs
 - keep module output ports.
- flatten
 - call 'flatten -wb; opt_expr -keepdc -undriven;;' on the miter circuit.

G.119 mutate - generate or apply design mutations

```
mutate -list N [options] [selection]
```

Create a list of N mutations using an even sampling.

```
-o filename
    Write list to this file instead of console output

-s filename
    Write a list of all src tags found in the design to the specified file

-seed N
    RNG seed for selecting mutations

-none
    Include a "none" mutation in the output

-ctrl name width value
    Add -ctrl options to the output. Use 'value' for first mutation, then
    simply count up from there.

-mode name
-module name
-cell name
-port name
-portbit int
-ctrlbit int
-wire name
-wirebit int
-src string
    Filter list of mutation candidates to those matching
    the given parameters.

-cfg option int
    Set a configuration option. Options available:
    weight_pq_w weight_pq_b weight_pq_c weight_pq_s
    weight_pq_mw weight_pq_mb weight_pq_mc weight_pq_ms
    weight_cover pick_cover_prcnt
```

```
mutate -mode MODE [options]
```

Apply the given mutation.

```
-ctrl name width value
    Add a control signal with the given name and width. The mutation is
    activated if the control signal equals the given value.

-module name
-cell name
-port name
```

(continues on next page)

(continued from previous page)

```

-portbit int
-ctrlbit int
    Mutation parameters, as generated by 'mutate -list N'.

-wire name
-wirebit int
-src string
    Ignored. (They are generated by -list for documentation purposes.)

```

G.120 muxcover - cover trees of MUX cells with wider MUXes

```

muxcover [options] [selection]

```

Cover trees of `$_MUX_` cells with `$_MUX{4,8,16}_` cells

```

-mux4[=cost], -mux8[=cost], -mux16[=cost]
    Cover $_MUX_ trees using the specified types of MUXes (with optional
    integer costs). If none of these options are given, the effect is the
    same as if all of them are.
    Default costs: $_MUX4_ = 220, $_MUX8_ = 460,
                  $_MUX16_ = 940

-mux2=cost
    Use the specified cost for $_MUX_ cells when making covering decisions.
    Default cost: $_MUX_ = 100

-dmux=cost
    Use the specified cost for $_MUX_ cells used in decoders.
    Default cost: 90

-nocode
    Do not insert decoder logic. This reduces the number of possible
    substitutions, but guarantees that the resulting circuit is not
    less efficient than the original circuit.

-nopartial
    Do not consider mappings that use $_MUX<N>_ to select from less
    than <N> different signals.

```

G.121 muxpack - `$mux/$pmux` cascades to `$pmux`

```

muxpack [selection]

```

This pass converts cascaded chains of `$pmux` cells (e.g. those created from case constructs) and `$mux` cells (e.g. those created by if-else constructs) into `$pmux` cells.

(continues on next page)

(continued from previous page)

This optimisation is conservative --- it will only pack \$mux or \$pmux cells whose select lines are driven by '\$eq' cells with other such cells if it can be certain that their select inputs are mutually exclusive.

G.122 nlutmap - map to LUTs of different sizes

```
nlutmap [options] [selection]
```

This pass uses successive calls to 'abc' to map to an architecture. That provides a small number of differently sized LUTs.

```
-luts N_1,N_2,N_3,...
```

The number of LUTs with 1, 2, 3, ... inputs that are available in the target architecture.

```
-assert
```

Create an error if not all logic can be mapped

Excess logic that does not fit into the specified LUTs is mapped back to generic logic gates (\$_AND_, etc.).

G.123 onehot - optimize \$eq cells for onehot signals

```
onehot [options] [selection]
```

This pass optimizes \$eq cells that compare one-hot signals against constants

```
-v, -vv
```

verbose output

G.124 opt - perform simple optimizations

```
opt [options] [selection]
```

This pass calls all the other opt_* passes in a useful order. This performs a series of trivial optimizations and cleanups. This pass executes the other passes in the following order:

```
opt_expr [-mux_undef] [-mux_bool] [-undriven] [-noclkinv] [-fine] [-full] [-keepdc]
opt_merge [-share_all] -nomux

do
    opt_muxtree
    opt_reduce [-fine] [-full]
    opt_merge [-share_all]
```

(continues on next page)

(continued from previous page)

```

    opt_share  (-full only)
    opt_dff [-nodffe] [-nosdff] [-keepdc] [-sat]  (except when called with -noff)
    opt_clean [-purge]
    opt_expr [-mux_undef] [-mux_bool] [-undriven] [-noclkinv] [-fine] [-full] [-
↪keepdc]
    while <changed design>

```

When called with -fast the following script is used instead:

```

do
    opt_expr [-mux_undef] [-mux_bool] [-undriven] [-noclkinv] [-fine] [-full] [-
↪keepdc]
    opt_merge [-share_all]
    opt_dff [-nodffe] [-nosdff] [-keepdc] [-sat]  (except when called with -noff)
    opt_clean [-purge]
    while <changed design in opt_dff>

```

Note: Options in square brackets (such as [-keepdc]) are passed through to the opt_* commands when given to 'opt'.

G.125 opt_clean - remove unused cells and wires

```
opt_clean [options] [selection]
```

This pass identifies wires and cells that are unused and removes them. Other passes often remove cells but leave the wires in the design or reconnect the wires but leave the old cells in the design. This pass can be used to clean up after the passes that do the actual work.

This pass only operates on completely selected modules without processes.

```

-purge
    also remove internal nets if they have a public name

```

G.126 opt_demorgan - Optimize reductions with DeMorgan equivalents

```
opt_demorgan [selection]
```

This pass pushes inverters through \$reduce_* cells if this will reduce the overall gate count of the circuit

G.127 opt_dff - perform DFF optimizations

```
opt_dff [-nodffe] [-nosdff] [-keepdc] [-sat] [selection]
```

This pass converts flip-flops to a more suitable type by merging clock enables and synchronous reset multiplexers, removing unused control inputs, or potentially removes the flip-flop altogether, converting it to a constant driver.

```
-nodffe
    disables dff -> dffe conversion, and other transforms recognizing clock
    enable

-nosdff
    disables dff -> sdff conversion, and other transforms recognizing sync
    resets

-simple-dffe
    only enables clock enable recognition transform for obvious cases

-sat
    additionally invoke SAT solver to detect and remove flip-flops (with
    non-constant inputs) that can also be replaced with a constant driver

-keepdc
    some optimizations change the behavior of the circuit with respect to
    don't-care bits. for example in 'a+0' a single x-bit in 'a' will cause
    all result bits to be set to x. this behavior changes when 'a+0' is
    replaced by 'a'. the -keepdc option disables all such optimizations.
```

G.128 opt_expr - perform const folding and simple expression rewriting

```
opt_expr [options] [selection]
```

This pass performs const folding on internal cell types with constant inputs. It also performs some simple expression rewriting.

```
-mux_undef
    remove 'undef' inputs from $mux, $pmux and $_MUX_ cells

-mux_bool
    replace $mux cells with inverters or buffers when possible

-undriven
    replace undriven nets with undef (x) constants

-noclkinv
    do not optimize clock inverters by changing FF types

-fine
```

(continues on next page)

(continued from previous page)

```
perform fine-grain optimizations

-full
    alias for -mux_undef -mux_bool -undriven -fine

-keepdc
    some optimizations change the behavior of the circuit with respect to
    don't-care bits. for example in 'a+0' a single x-bit in 'a' will cause
    all result bits to be set to x. this behavior changes when 'a+0' is
    replaced by 'a'. the -keepdc option disables all such optimizations.
```

G.129 opt_ffinv - push inverters through FFs

```
opt_ffinv [selection]
```

This pass pushes inverters to the other side of a FF when they can be merged into LUTs on the other side.

G.130 opt_lut - optimize LUT cells

```
opt_lut [options] [selection]
```

This pass combines cascaded \$lut cells with unused inputs.

```
-dlogic <type>:<cell-port>=<LUT-input>[:<cell-port>=<LUT-input>...]
    preserve connections to dedicated logic cell <type> that has ports
    <cell-port> connected to LUT inputs <LUT-input>. this includes
    the case where both LUT and dedicated logic input are connected to
    the same constant.

-limit N
    only perform the first N combines, then stop. useful for debugging.
```

G.131 opt_lut_ins - discard unused LUT inputs

```
opt_lut_ins [options] [selection]
```

This pass removes unused inputs from LUT cells (that is, inputs that can not influence the output signal given this LUT's value). While such LUTs cannot be directly emitted by ABC, they can be a result of various post-ABC transformations, such as mapping wide LUTs (not all sub-LUTs will use the full set of inputs) or optimizations such as xilinx_dffopt.

```
-tech <technology>
```

(continues on next page)

(continued from previous page)

Instead of generic \$lut cells, operate on LUT cells specific to the given technology. Valid values are: xilinx, ecp5, gowin.

G.132 opt_mem - optimize memories

```
opt_mem [options] [selection]
```

This pass performs various optimizations on memories in the design.

G.133 opt_mem_feedback - convert memory read-to-write port feedback paths to write enables

```
opt_mem_feedback [selection]
```

This pass detects cases where an asynchronous read port is only connected via a mux tree to a write port with the same address. When such a connection is found, it is replaced with a new condition on an enable signal, allowing for removal of the read port.

G.134 opt_mem_priority - remove priority relations between write ports that can never collide

```
opt_mem_priority [selection]
```

This pass detects cases where one memory write port has priority over another even though they can never collide with each other -- ie. there can never be a situation where a given memory bit is written by both ports at the same time, for example because of always-different addresses, or mutually exclusive enable signals. In such cases, the priority relation is removed.

G.135 opt_mem_widen - optimize memories where all ports are wide

```
opt_mem_widen [options] [selection]
```

This pass looks for memories where all ports are wide and adjusts the base memory width up until that stops being the case.

G.136 `opt_merge` - consolidate identical cells

```
opt_merge [options] [selection]
```

This pass identifies cells with identical type and input signals. Such cells are then merged to one cell.

```
-nomux
```

Do not merge MUX cells.

```
-share_all
```

Operate on all cell types, not just built-in types.

```
-keepdc
```

Do not merge flipflops with don't-care bits in their initial value.

G.137 `opt_muxtree` - eliminate dead trees in multiplexer trees

```
opt_muxtree [selection]
```

This pass analyzes the control signals for the multiplexer trees in the design and identifies inputs that can never be active. It then removes this dead branches from the multiplexer trees.

This pass only operates on completely selected modules without processes.

G.138 `opt_reduce` - simplify large MUXes and AND/OR gates

```
opt_reduce [options] [selection]
```

This pass performs two interlinked optimizations:

1. it consolidates trees of large AND gates or OR gates and eliminates duplicated inputs.

2. it identifies duplicated inputs to MUXes and replaces them with a single input with the original control signals OR'ed together.

```
-fine
```

perform fine-grain optimizations

```
-full
```

alias for -fine

G.139 `opt_share` - merge mutually exclusive cells of the same type that share an input signal

```
opt_share [selection]
```

This pass identifies mutually exclusive cells of the same type that:

- (a) share an input signal,
- (b) drive the same `$mux`, `$_MUX_`, or `$pmux` multiplexing cell,

allowing the cell to be merged and the multiplexer to be moved from multiplexing its output to multiplexing the non-shared input signals.

G.140 `paramap` - renaming cell parameters

```
paramap [options] [selection]
```

This command renames cell parameters and/or maps key/value pairs to other key/value pairs.

```
-tocase <name>
    Match attribute names case-insensitively and set it to the specified
    name.

-rename <old_name> <new_name>
    Rename attributes as specified

-map <old_name>=<old_value> <new_name>=<new_value>
    Map key/value pairs as indicated.

-imap <old_name>=<old_value> <new_name>=<new_value>
    Like -map, but use case-insensitive match for <old_value> when
    it is a string value.

-remove <name>=<value>
    Remove attributes matching this pattern.
```

For example, mapping Diamond-style ECP5 "init" attributes to Yosys-style:

```
paramap -tocase INIT t:LUT4
```

G.141 peepopt - collection of peephole optimizers

```
peepopt [options] [selection]
```

This pass applies a collection of peephole optimizers to the current design.

G.142 plugin - load and list loaded plugins

```
plugin [options]
```

Load and list loaded plugins.

```
-i <plugin_filename>
    Load (install) the specified plugin.

-a <alias_name>
    Register the specified alias name for the loaded plugin

-l
    List loaded plugins
```

G.143 pmux2shiftx - transform \$pmux cells to \$shiftx cells

```
pmux2shiftx [options] [selection]
```

This pass transforms \$pmux cells to \$shiftx cells.

```
-v, -vv
    verbose output

-min_density <percentage>
    specifies the minimum density for the shifter
    default: 50

-min_choices <int>
    specified the minimum number of choices for a control signal
    default: 3

-onehot ignore|pmux|shiftx
    select strategy for one-hot encoded control signals
    default: pmux

-norange
    disable $sub inference for "range decoders"
```

G.144 pmuxtree - transform \$pmux cells to trees of \$mux cells

```
pmuxtree [selection]
```

This pass transforms \$pmux cells to trees of \$mux cells.

G.145 portlist - list (top-level) ports

```
portlist [options] [selection]
```

This command lists all module ports found in the selected modules.

If no selection is provided then it lists the ports on the top module.

```
-m
  print verilog blackbox module definitions instead of port lists
```

G.146 prep - generic synthesis script

```
prep [options]
```

This command runs a conservative RTL synthesis. A typical application for this is the preparation stage of a verification flow. This command does not operate on partly selected designs.

```
-top <module>
  use the specified module as top module (default='top')

-auto-top
  automatically determine the top of the design hierarchy

-flatten
  flatten the design before synthesis. this will pass '-auto-top' to
  'hierarchy' if no top module is specified.

-ifx
  passed to 'proc'. uses verilog simulation behavior for verilog if/case
  undef handling. this also prevents 'wreduce' from being run.

-memx
  simulate verilog simulation behavior for out-of-bounds memory accesses
  using the 'memory_memx' pass.

-nomem
  do not run any of the memory_* passes

-rdff
  call 'memory_dff'. This enables merging of FFs into
```

(continues on next page)

(continued from previous page)

```
memory read ports.

-nokeepdc
  do not call opt_* with -keepdc

-run <from_label>[:<to_label>]
  only run the commands between the labels (see below). an empty
  from label is synonymous to 'begin', and empty to label is
  synonymous to the end of the command list.
```

The following commands are executed by this synthesis command:

```
begin:
  hierarchy -check [-top <top> | -auto-top]

coarse:
  proc [-ifx]
  flatten    (if -flatten)
  opt_expr -keepdc
  opt_clean
  check
  opt -noff -keepdc
  wreduce -keepdc [-memx]
  memory_dff    (if -rdff)
  memory_memx    (if -memx)
  opt_clean
  memory_collect
  opt -noff -keepdc -fast

check:
  stat
  check
```

G.147 printattrs - print attributes of selected objects

```
printattrs [selection]
```

Print all attributes of the selected objects.

G.148 proc - translate processes to netlists

```
proc [options] [selection]
```

This pass calls all the other `proc_*` passes in the most common order.

```
proc_clean
proc_rmdead
proc_prune
proc_init
proc_arst
proc_rom
proc_mux
proc_dlatch
proc_dff
proc_memwr
proc_clean
opt_expr -keepdc
```

This replaces the processes in the design with multiplexers, flip-flops and latches.

The following options are supported:

```
-nomux
    Will omit the proc_mux pass.

-norom
    Will omit the proc_rom pass.

-global_arst [!]<netname>
    This option is passed through to proc_arst.

-ifx
    This option is passed through to proc_mux. proc_rmdead is not
    executed in -ifx mode.

-noopt
    Will omit the opt_expr pass.
```

G.149 proc_arst - detect asynchronous resets

```
proc_arst [-global_arst [!]<netname>] [selection]
```

This pass identifies asynchronous resets in the processes and converts them to a different internal representation that is suitable for generating flip-flop cells with asynchronous resets.

```
-global_arst [!]<netname>
    In modules that have a net with the given name, use this net as async
```

(continues on next page)

(continued from previous page)

```
reset for registers that have been assign initial values in their
declaration ('reg foobar = constant_value;'). Use the '!' modifier for
active low reset signals. Note: the frontend stores the default value
in the 'init' attribute on the net.
```

G.150 `proc_clean` - remove empty parts of processes

```
proc_clean [options] [selection]

-quiet
    do not print any messages.
```

This pass removes empty parts of processes and ultimately removes a process if it contains only empty structures.

G.151 `proc_dff` - extract flip-flops from processes

```
proc_dff [selection]
```

This pass identifies flip-flops in the processes and converts them to d-type flip-flop cells.

G.152 `proc_dlatch` - extract latches from processes

```
proc_dlatch [selection]
```

This pass identifies latches in the processes and converts them to d-type latches.

G.153 `proc_init` - convert initial block to init attributes

```
proc_init [selection]
```

This pass extracts the 'init' actions from processes (generated from Verilog 'initial' blocks) and sets the initial value to the 'init' attribute on the respective wire.

G.154 `proc_memwr` - extract memory writes from processes

```
proc_memwr [selection]
```

This pass converts memory writes in processes into `$memwr` cells.

G.155 `proc_mux` - convert decision trees to multiplexers

```
proc_mux [options] [selection]
```

This pass converts the decision trees in processes (originating from if-else and case statements) to trees of multiplexer cells.

```
-ifx
    Use Verilog simulation behavior with respect to undef values in
    'case' expressions and 'if' conditions.
```

G.156 `proc_prune` - remove redundant assignments

```
proc_prune [selection]
```

This pass identifies assignments in processes that are always overwritten by a later assignment to the same signal and removes them.

G.157 `proc_rmdead` - eliminate dead trees in decision trees

```
proc_rmdead [selection]
```

This pass identifies unreachable branches in decision trees and removes them.

G.158 `proc_rom` - convert switches to ROMs

```
proc_rom [selection]
```

This pass converts switches into read-only memories when appropriate.

G.159 qbfsat - solve a 2QBF-SAT problem in the circuit

```
qbfsat [options] [selection]
```

This command solves an "exists-forall" 2QBF-SAT problem defined over the currently selected module. Existentially-quantified variables are declared by assigning a wire "\$anyconst". Universally-quantified variables may be explicitly declared by assigning a wire "\$allconst", but module inputs will be treated as universally-quantified variables by default.

```
-nocleanup
```

Do not delete temporary files and directories. Useful for debugging.

```
-dump-final-smt2 <file>
```

Pass the --dump-smt2 option to yosys-smtbmc.

```
-assume-outputs
```

Add an "\$assume" cell for the conjunction of all one-bit module output wires.

```
-assume-negative-polarity
```

When adding \$assume cells for one-bit module output wires, assume they are negative polarity signals and should always be low, for example like the miters created with the `miter` command.

```
-nooptimize
```

Ignore "\minimize" and "\maximize" attributes, do not emit "(maximize)" or "(minimize)" in the SMT-LIBv2, and generally make no attempt to optimize anything.

```
-nobisection
```

If a wire is marked with the "\minimize" or "\maximize" attribute, do not attempt to optimize that value with the default iterated solving and threshold bisection approach. Instead, have yosys-smtbmc emit a "(minimize)" or "(maximize)" command in the SMT-LIBv2 output and hope that the solver supports optimizing quantified bitvector problems.

```
-solver <solver>
```

Use a particular solver. Choose one of: "z3", "yices", "cvc4" and "cvc5". (default: yices)

```
-solver-option <name> <value>
```

Set the specified solver option in the SMT-LIBv2 problem file.

```
-timeout <value>
```

Set the per-iteration timeout in seconds.
(default: no timeout)

```
-00, -01, -02
```

Control the use of ABC to simplify the QBF-SAT problem before solving.

```
-sat
```

(continues on next page)

(continued from previous page)

```

    Generate an error if the solver does not return "sat".

-unsat
    Generate an error if the solver does not return "unsat".

-show-smtbmc
    Print the output from yosys-smtbmc.

-specialize
    If the problem is satisfiable, replace each "$anyconst" cell with its
    corresponding constant value from the model produced by the solver.

-specialize-from-file <solution file>
    Do not run the solver, but instead only attempt to replace each
    "$anyconst" cell in the current module with a constant value provided
    by the specified file.

-write-solution <solution file>
    If the problem is satisfiable, write the corresponding constant value
    for each "$anyconst" cell from the model produced by the solver to the
    specified file.

```

G.160 qwp - quadratic wirelength placer

```
qwp [options] [selection]
```

This command runs quadratic wirelength placement on the selected modules and annotates the cells in the design with 'qwp_position' attributes.

```

-ltr
    Add left-to-right constraints: constrain all inputs on the left border
    outputs to the right border.

-alpha
    Add constraints for inputs/outputs to be placed in alphanumerical
    order along the y-axis (top-to-bottom).

-grid N
    Number of grid divisions in x- and y-direction. (default=16)

-dump <html_file_name>
    Dump a protocol of the placement algorithm to the html file.

-v
    Verbose solver output for profiling or debugging

```

Note: This implementation of a quadratic wirelength placer uses exact dense matrix operations. It is only a toy-placer for small circuits.

G.161 read - load HDL designs

```
read {-vlog95|-vlog2k|-sv2005|-sv2009|-sv2012|-sv|-formal} <verilog-file>..
```

Load the specified Verilog/SystemVerilog files. (Full SystemVerilog support is only available via Verific.)

Additional `-D<macro>[=<value>]` options may be added after the option indicating the language version (and before file names) to set additional verilog defines.

```
read {-liberty} <liberty-file>..
```

Load the specified Liberty files.

```
-lib
    only create empty blackbox modules
```

```
read {-f|-F} <command-file>
```

Load and execute the specified command file. (Requires Verific.)
Check verific command for more information about supported commands in file.

```
read -define <macro>[=<value>]..
```

Set global Verilog/SystemVerilog defines.

```
read -undef <macro>..
```

Unset global Verilog/SystemVerilog defines.

```
read -incdir <directory>
```

Add directory to global Verilog/SystemVerilog include directories.

```
read -verific
read -noverific
```

Subsequent calls to 'read' will either use or not use Verific. Calling 'read' with `-verific` will result in an error on Yosys binaries that are built without Verific support. The default is to use Verific if it is available.

G.162 read_aiger - read AIGER file

```
read_aiger [options] [filename]
```

Load module from an AIGER file into the current design.

```
-module_name <module_name>
    name of module to be created (default: <filename>)

-clk_name <wire_name>
    if specified, AIGER latches to be transformed into $_DFF_P_ cells
    clocked by wire of this name. otherwise, $_FF_ cells will be used

-map <filename>
    read file with port and latch symbols

-wideports
    merge ports that match the pattern 'name[int]' into a single
    multi-bit port 'name'

-xaiger
    read XAIGER extensions
```

G.163 read_blif - read BLIF file

```
read_blif [options] [filename]
```

Load modules from a BLIF file into the current design.

```
-sop
    Create $sop cells instead of $lut cells

-wideports
    Merge ports that match the pattern 'name[int]' into a single
    multi-bit port 'name'.
```

G.164 read_ilang - (deprecated) alias of read_rtlil

See ``help read_rtlil``.

G.165 read_json - read JSON file

```
read_json [filename]
```

Load modules from a JSON file into the current design See "help write_json" for a description of the file format.

G.166 read_liberty - read cells from liberty file

```
read_liberty [filename]
```

Read cells from liberty file as modules into current design.

```
-lib
    only create empty blackbox modules

-wb
    mark imported cells as whiteboxes

-nooverwrite
    ignore re-definitions of modules. (the default behavior is to
    create an error message if the existing module is not a blackbox
    module, and overwrite the existing module if it is a blackbox module.)

-overwrite
    overwrite existing modules with the same name

-ignore_miss_func
    ignore cells with missing function specification of outputs

-ignore_miss_dir
    ignore cells with a missing or invalid direction
    specification on a pin

-ignore_miss_data_latch
    ignore latches with missing data and/or enable pins

-setattr <attribute_name>
    set the specified attribute (to the value 1) on all loaded modules
```

G.167 read_rtlil - read modules from RTLIL file

```
read_rtlil [filename]
```

Load modules from an RTLIL file to the current design. (RTLIL is a text representation of a design in yosys's internal format.)

```
-nooverwrite
```

ignore re-definitions of modules. (the default behavior is to create an error message if the existing module is not a blackbox module, and overwrite the existing module if it is a blackbox module.)

```
-overwrite
```

overwrite existing modules with the same name

```
-lib
```

only create empty blackbox modules

G.168 read_verilog - read modules from Verilog file

```
read_verilog [options] [filename]
```

Load modules from a Verilog file to the current design. A large subset of Verilog-2005 is supported.

```
-sv
```

enable support for SystemVerilog features. (only a small subset of SystemVerilog is supported)

```
-formal
```

enable support for SystemVerilog assertions and some Yosys extensions
replace the implicit -D SYNTHESIS with -D FORMAL

```
-nosynthesis
```

don't add implicit -D SYNTHESIS

```
-noassert
```

ignore assert() statements

```
-noassume
```

ignore assume() statements

```
-norestrict
```

ignore restrict() statements

```
-assume-asserts
```

treat all assert() statements like assume() statements

```
-assert-assumes
```

treat all assume() statements like assert() statements

(continues on next page)

(continued from previous page)

```
-debug
    alias for -dump_ast1 -dump_ast2 -dump_vlog1 -dump_vlog2 -yydebug

-dump_ast1
    dump abstract syntax tree (before simplification)

-dump_ast2
    dump abstract syntax tree (after simplification)

-no_dump_ptr
    do not include hex memory addresses in dump (easier to diff dumps)

-dump_vlog1
    dump ast as Verilog code (before simplification)

-dump_vlog2
    dump ast as Verilog code (after simplification)

-dump_rtlil
    dump generated RTLIL netlist

-yydebug
    enable parser debug output

-nolatches
    usually latches are synthesized into logic loops
    this option prohibits this and sets the output to 'x'
    in what would be the latches hold condition

    this behavior can also be achieved by setting the
    'nolatches' attribute on the respective module or
    always block.

-nomem2reg
    under certain conditions memories are converted to registers
    early during simplification to ensure correct handling of
    complex corner cases. this option disables this behavior.

    this can also be achieved by setting the 'nomem2reg'
    attribute on the respective module or register.

    This is potentially dangerous. Usually the front-end has good
    reasons for converting an array to a list of registers.
    Prohibiting this step will likely result in incorrect synthesis
    results.

-mem2reg
    always convert memories to registers. this can also be
    achieved by setting the 'mem2reg' attribute on the respective
    module or register.
```

(continues on next page)

(continued from previous page)

```
-nomeminit
    do not infer $meminit cells and instead convert initialized
    memories to registers directly in the front-end.

-ppdump
    dump Verilog code after pre-processor

-nopp
    do not run the pre-processor

-nodpi
    disable DPI-C support

-noblackbox
    do not automatically add a (* blackbox *) attribute to an
    empty module.

-lib
    only create empty blackbox modules. This implies -DBLACKBOX.
    modules with the (* whitebox *) attribute will be preserved.
    (* lib_whitebox *) will be treated like (* whitebox *).

-nowb
    delete (* whitebox *) and (* lib_whitebox *) attributes from
    all modules.

-specify
    parse and import specify blocks

-noopt
    don't perform basic optimizations (such as const folding) in the
    high-level front-end.

-icells
    interpret cell types starting with '$' as internal cell types

-pwires
    add a wire for each module parameter

-nooverwrite
    ignore re-definitions of modules. (the default behavior is to
    create an error message if the existing module is not a black box
    module, and overwrite the existing module otherwise.)

-overwrite
    overwrite existing modules with the same name

-defer
    only read the abstract syntax tree and defer actual compilation
    to a later 'hierarchy' command. Useful in cases where the default
    parameters of modules yield invalid or not synthesizable code.
```

(continues on next page)

(continued from previous page)

```
-noautowire
    make the default of `default_nettype be "none" instead of "wire".

-setattr <attribute_name>
    set the specified attribute (to the value 1) on all loaded modules

-Dname[=definition]
    define the preprocessor symbol 'name' and set its optional value
    'definition'

-Idir
    add 'dir' to the directories which are used when searching include
    files
```

The command 'verilog_defaults' can be used to register default options for subsequent calls to 'read_verilog'.

Note that the Verilog frontend does a pretty good job of processing valid verilog input, but has not very good error reporting. It generally is recommended to use a simulator (for example Icarus Verilog) for checking the syntax of the code, rather than to rely on read_verilog for that.

Depending on if read_verilog is run in -formal mode, either the macro SYNTHESIS or FORMAL is defined automatically, unless -nosynthesis is used. In addition, read_verilog always defines the macro YOSYS.

See the Yosys README file for a list of non-standard Verilog features supported by the Yosys Verilog front-end.

G.169 recover_names - Execute a lossy mapping command and recover original netnames

```
recover_names [command]
```

This pass executes a lossy mapping command and uses a combination of simulation to find candidate equivalences and SAT to recover exact original net names.

G.170 rename - rename object in the design

```
rename old_name new_name
```

Rename the specified object. Note that selection patterns are not supported by this command.

```
rename -output old_name new_name
```

(continues on next page)

(continued from previous page)

Like above, but also make the wire an output. This will fail if the object is not a wire.

```
rename -src [selection]
```

Assign names auto-generated from the src attribute to all selected wires and cells with private names.

```
rename -wire [selection] [-suffix <suffix>]
```

Assign auto-generated names based on the wires they drive to all selected cells with private names. Ignores cells driving privately named wires. By default, the cell is named after the wire with the cell type as suffix. The -suffix option can be used to set the suffix to the given string instead.

```
rename -enumerate [-pattern <pattern>] [selection]
```

Assign short auto-generated names to all selected wires and cells with private names. The -pattern option can be used to set the pattern for the new names. The character % in the pattern is replaced with a integer number. The default pattern is '%_-'.

```
rename -witness
```

Assigns auto-generated names to all \$any*/\$all* output wires and containing cells that do not have a public name. This ensures that, during formal verification, a solver-found trace can be fully specified using a public hierarchical names.

```
rename -hide [selection]
```

Assign private names (the ones with \$-prefix) to all selected wires and cells with public names. This ignores all selected ports.

```
rename -top new_name
```

Rename top module.

```
rename -scramble-name [-seed <seed>] [selection]
```

Assign randomly-generated names to all selected wires and cells. The seed option can be used to change the random number generator seed from the default, but it must be non-zero.

G.171 rmparts - remove module ports with no connections

```
rmparts [selection]
```

This pass identifies ports in the selected modules which are not used or driven and removes them.

G.172 sat - solve a SAT problem in the circuit

```
sat [options] [selection]
```

This command solves a SAT problem defined over the currently selected circuit and additional constraints passed as parameters.

```
-all
    show all solutions to the problem (this can grow exponentially, use
    -max <N> instead to get <N> solutions)

-max <N>
    like -all, but limit number of solutions to <N>

-enable_undef
    enable modeling of undef value (aka 'x-bits')
    this option is implied by -set-def, -set-undef et. cetera

-max_undef
    maximize the number of undef bits in solutions, giving a better
    picture of which input bits are actually vital to the solution.

-set <signal> <value>
    set the specified signal to the specified value.

-set-def <signal>
    add a constraint that all bits of the given signal must be defined

-set-any-undef <signal>
    add a constraint that at least one bit of the given signal is undefined

-set-all-undef <signal>
    add a constraint that all bits of the given signal are undefined

-set-def-inputs
    add -set-def constraints for all module inputs

-set-def-formal
    add -set-def constraints for formal $anyinit, $anyconst, $anyseq cells

-show <signal>
    show the model for the specified signal. if no -show option is
    passed then a set of signals to be shown is automatically selected.
```

(continues on next page)

(continued from previous page)

```

-show-inputs, -show-outputs, -show-ports
    add all module (input/output) ports to the list of shown signals

-show-regs, -show-public, -show-all
    show all registers, show signals with 'public' names, show all signals

-ignore_div_by_zero
    ignore all solutions that involve a division by zero

-ignore_unknown_cells
    ignore all cells that can not be matched to a SAT model

```

The following options can be used to set up a sequential problem:

```

-seq <N>
    set up a sequential problem with <N> time steps. The steps will
    be numbered from 1 to N.

    note: for large <N> it can be significantly faster to use
    -tempinduct-baseonly -maxsteps <N> instead of -seq <N>.

-set-at <N> <signal> <value>
-unset-at <N> <signal>
    set or unset the specified signal to the specified value in the
    given timestep. this has priority over a -set for the same signal.

-set-assumes
    set all assumptions provided via $assume cells

-set-def-at <N> <signal>
-set-any-undef-at <N> <signal>
-set-all-undef-at <N> <signal>
    add undef constraints in the given timestep.

-set-init <signal> <value>
    set the initial value for the register driving the signal to the value

-set-init-undef
    set all initial states (not set using -set-init) to undef

-set-init-def
    do not force a value for the initial state but do not allow undef

-set-init-zero
    set all initial states (not set using -set-init) to zero

-dump_vcd <vcd-file-name>
    dump SAT model (counter example in proof) to VCD file

-dump_json <json-file-name>
    dump SAT model (counter example in proof) to a WaveJSON file.

```

(continues on next page)

(continued from previous page)

```
-dump_cnf <cnf-file-name>
    dump CNF of SAT problem (in DIMACS format). in temporal induction
    proofs this is the CNF of the first induction step.
```

The following additional options can be used to set up a proof. If also `-seq` is passed, a temporal induction proof is performed.

```
-tempinduct
    Perform a temporal induction proof. In a temporal induction proof it is
    proven that the condition holds forever after the number of time steps
    specified using -seq.
```

```
-tempinduct-def
    Perform a temporal induction proof. Assume an initial state with all
    registers set to defined values for the induction step.
```

```
-tempinduct-baseonly
    Run only the basecase half of temporal induction (requires -maxsteps)
```

```
-tempinduct-inductonly
    Run only the induction half of temporal induction
```

```
-tempinduct-skip <N>
    Skip the first <N> steps of the induction proof.
```

note: this will assume that the base case holds for <N> steps.
this must be proven independently with "`-tempinduct-baseonly`
`-maxsteps <N>`". Use `-initsteps` if you just want to set a
minimal induction length.

```
-prove <signal> <value>
    Attempt to proof that <signal> is always <value>.
```

```
-prove-x <signal> <value>
    Like -prove, but an undef (x) bit in the lhs matches any value on
    the right hand side. Useful for equivalence checking.
```

```
-prove-asserts
    Prove that all asserts in the design hold.
```

```
-prove-skip <N>
    Do not enforce the prove-condition for the first <N> time steps.
```

```
-maxsteps <N>
    Set a maximum length for the induction.
```

```
-initsteps <N>
    Set initial length for the induction.
    This will speed up the search of the right induction length
    for deep induction proofs.
```

(continues on next page)

(continued from previous page)

```

-stepsizesize <N>
    Increase the size of the induction proof in steps of <N>.
    This will speed up the search of the right induction length
    for deep induction proofs.

-timeout <N>
    Maximum number of seconds a single SAT instance may take.

-verify
    Return an error and stop the synthesis script if the proof fails.

-verify-no-timeout
    Like -verify but do not return an error for timeouts.

-falsify
    Return an error and stop the synthesis script if the proof succeeds.

-falsify-no-timeout
    Like -falsify but do not return an error for timeouts.

```

G.173 scatter - add additional intermediate nets

```
scatter [selection]
```

This command adds additional intermediate nets on all cell ports. This is used for testing the correct use of the SigMap helper in passes. If you don't know what this means: don't worry -- you only need this pass when testing your own extensions to Yosys.

Use the `opt_clean` command to get rid of the additional nets.

G.174 scc - detect strongly connected components (logic loops)

```
scc [options] [selection]
```

This command identifies strongly connected components (aka logic loops) in the design.

```

-expect <num>
    expect to find exactly <num> SCCs. A different number of SCCs will
    produce an error.

-max_depth <num>
    limit to loops not longer than the specified number of cells. This
    can e.g. be useful in identifying small local loops in a module that
    implements one large SCC.

```

(continues on next page)

(continued from previous page)

```

-nofeedback
    do not count cells that have their output fed back into one of their
    inputs as single-cell scc.

-all_cell_types
    Usually this command only considers internal non-memory cells. With
    this option set, all cells are considered. For unknown cells all ports
    are assumed to be bidirectional 'inout' ports.

-set_attr <name> <value>
    set the specified attribute on all cells that are part of a logic
    loop. the special token {} in the value is replaced with a unique
    identifier for the logic loop.

-select
    replace the current selection with a selection of all cells and wires
    that are part of a found logic loop

-specify
    examine specify rules to detect logic loops in whitebox/blackbox cells

```

G.175 scratchpad - get/set values in the scratchpad

```
scratchpad [options]
```

This pass allows to read and modify values from the scratchpad of the current design. Options:

```

-get <identifier>
    print the value saved in the scratchpad under the given identifier.

-set <identifier> <value>
    save the given value in the scratchpad under the given identifier.

-unset <identifier>
    remove the entry for the given identifier from the scratchpad.

-copy <identifier_from> <identifier_to>
    copy the value of the first identifier to the second identifier.

-assert <identifier> <value>
    assert that the entry for the given identifier is set to the given
    value.

-assert-set <identifier>
    assert that the entry for the given identifier exists.

-assert-unset <identifier>
    assert that the entry for the given identifier does not exist.

```

(continues on next page)

(continued from previous page)

The identifier may not contain whitespace. By convention, it is usually prefixed by the name of the pass that uses it, e.g. 'opt.did_something'. If the value contains whitespace, it must be enclosed in double quotes.

G.176 script - execute commands from file or wire

```
script <filename> [<from_label>:<to_label>]
script -scriptwire [selection]
```

This command executes the yosys commands in the specified file (default behaviour), or commands embedded in the constant text value connected to the selected wires.

In the default (file) case, the 2nd argument can be used to only execute the section of the file between the specified labels. An empty from label is synonymous with the beginning of the file and an empty to label is synonymous with the end of the file.

If only one label is specified (without ':') then only the block marked with that label (until the next label) is executed.

In "-scriptwire" mode, the commands on the selected wire(s) will be executed in the scope of (and thus, relative to) the wires' owning module(s). This '-module' mode can be exited by using the 'cd' command.

G.177 select - modify and view the list of selected objects

```
select [ -add | -del | -set <name> ] {-read <filename> | <selection>}
select [ -unset <name> ]
select [ <assert_option> ] {-read <filename> | <selection>}
select [ -list | -write <filename> | -count | -clear ]
select -module <modname>
```

Most commands use the list of currently selected objects to determine which part of the design to operate on. This command can be used to modify and view this list of selected objects.

Note that many commands support an optional [selection] argument that can be used to override the global selection for the command. The syntax of this optional argument is identical to the syntax of the <selection> argument described here.

```
-add, -del
    add or remove the given objects to the current selection.
    without this options the current selection is replaced.
```

(continues on next page)

(continued from previous page)

```
-set <name>
do not modify the current selection. instead save the new selection
under the given name (see @<name> below). to save the current selection,
use "select -set <name> %"

-unset <name>
do not modify the current selection. instead remove a previously saved
selection under the given name (see @<name> below).

-assert-none
do not modify the current selection. instead assert that the given
selection is empty. i.e. produce an error if any object or module
matching the selection is found.

-assert-any
do not modify the current selection. instead assert that the given
selection is non-empty. i.e. produce an error if no object or module
matching the selection is found.

-assert-count N
do not modify the current selection. instead assert that the given
selection contains exactly N objects.

-assert-max N
do not modify the current selection. instead assert that the given
selection contains less than or exactly N objects.

-assert-min N
do not modify the current selection. instead assert that the given
selection contains at least N objects.

-list
list all objects in the current selection

-write <filename>
like -list but write the output to the specified file

-read <filename>
read the specified file (written by -write)

-count
count all objects in the current selection

-clear
clear the current selection. this effectively selects the whole
design. it also resets the selected module (see -module). use the
command 'select *' to select everything but stay in the current module.

-none
create an empty selection. the current module is unchanged.

-module <modname>
```

(continues on next page)

(continued from previous page)

limit the current scope to the specified module.
 the difference between this and simply selecting the module
 is that all object names are interpreted relative to this
 module after this command until the selection is cleared again.

When this command is called without an argument, the current selection
 is displayed in a compact form (i.e. only the module name when a whole module
 is selected).

The <selection> argument itself is a series of commands for a simple stack
 machine. Each element on the stack represents a set of selected objects.
 After this commands have been executed, the union of all remaining sets
 on the stack is computed and used as selection for the command.

Pushing (selecting) object when not in -module mode:

```
<mod_pattern>
  select the specified module(s)

<mod_pattern>/<obj_pattern>
  select the specified object(s) from the module(s)
```

Pushing (selecting) object when in -module mode:

```
<obj_pattern>
  select the specified object(s) from the current module
```

By default, patterns will not match black/white-box modules or their
 contents. To include such objects, prefix the pattern with '='.

A <mod_pattern> can be a module name, wildcard expression (*, ?, [..])
 matching module names, or one of the following:

```
A:<pattern>, A:<pattern>=<pattern>
  all modules with an attribute matching the given pattern
  in addition to = also <, <=, >=, and > are supported

N:<pattern>
  all modules with a name matching the given pattern
  (i.e. 'N:' is optional as it is the default matching rule)
```

An <obj_pattern> can be an object name, wildcard expression, or one of
 the following:

```
w:<pattern>
  all wires with a name matching the given wildcard pattern

i:<pattern>, o:<pattern>, x:<pattern>
  all inputs (i:), outputs (o:) or any ports (x:) with matching names

s:<size>, s:<min>:<max>
  all wires with a matching width
```

(continues on next page)

(continued from previous page)

```

m:<pattern>
    all memories with a name matching the given pattern

c:<pattern>
    all cells with a name matching the given pattern

t:<pattern>
    all cells with a type matching the given pattern

p:<pattern>
    all processes with a name matching the given pattern

a:<pattern>
    all objects with an attribute name matching the given pattern

a:<pattern>=<pattern>
    all objects with a matching attribute name-value-pair.
    in addition to = also <, <=, >=, and > are supported

r:<pattern>, r:<pattern>=<pattern>
    cells with matching parameters. also with <, <=, >= and >.

n:<pattern>
    all objects with a name matching the given pattern
    (i.e. 'n:' is optional as it is the default matching rule)

@<name>
    push the selection saved prior with 'select -set <name> ...'

```

The following actions can be performed on the top sets on the stack:

```

%
    push a copy of the current selection to the stack

%%
    replace the stack with a union of all elements on it

%n
    replace top set with its invert

%u
    replace the two top sets on the stack with their union

%i
    replace the two top sets on the stack with their intersection

%d
    pop the top set from the stack and subtract it from the new top

%D
    like %d but swap the roles of two top sets on the stack

```

(continues on next page)

(continued from previous page)

```

%c
    create a copy of the top set from the stack and push it

%x[<num1>|*][.<num2>][:<rule>[:<rule>..]]
    expand top set <num1> num times according to the specified rules.
    (i.e. select all cells connected to selected wires and select all
    wires connected to selected cells) The rules specify which cell
    ports to use for this. the syntax for a rule is a '-' for exclusion
    and a '+' for inclusion, followed by an optional comma separated
    list of cell types followed by an optional comma separated list of
    cell ports in square brackets. a rule can also be just a cell or wire
    name that limits the expansion (is included but does not go beyond).
    select at most <num2> objects. a warning message is printed when this
    limit is reached. When '*' is used instead of <num1> then the process
    is repeated until no further object are selected.

%ci[<num1>|*][.<num2>][:<rule>[:<rule>..]]
%co[<num1>|*][.<num2>][:<rule>[:<rule>..]]
    similar to %x, but only select input (%ci) or output cones (%co)

%xe[...] %cie[...] %coe
    like %x, %ci, and %co but only consider combinatorial cells

%a
    expand top set by selecting all wires that are (at least in part)
    aliases for selected wires.

%s
    expand top set by adding all modules that implement cells in selected
    modules

%m
    expand top set by selecting all modules that contain selected objects

%M
    select modules that implement selected cells

%C
    select cells that implement selected modules

%R[<num>]
    select <num> random objects from top selection (default 1)

```

Example: the following command selects all wires that are connected to a 'GATE' input of a 'SWITCH' cell:

```
select */t:SWITCH %x:+[GATE] */t:SWITCH %d
```

G.178 setattr - set/unset attributes on objects

```
setattr [ -mod ] [ -set name value | -unset name ]... [selection]
```

Set/unset the given attributes on the selected objects. String values must be passed in double quotes (").

When called with `-mod`, this command will set and unset attributes on modules instead of objects within modules.

G.179 setparam - set/unset parameters on objects

```
setparam [ -type cell_type ] [ -set name value | -unset name ]... [selection]
```

Set/unset the given parameters on the selected cells. String values must be passed in double quotes (").

The `-type` option can be used to change the cell type of the selected cells.

G.180 setundef - replace undef values with defined constants

```
setundef [options] [selection]
```

This command replaces undef (x) constants with defined (0/1) constants.

`-undriven`

also set undriven nets to constant values

`-expose`

also expose undriven nets as inputs (use with `-undriven`)

`-zero`

replace with bits cleared (0)

`-one`

replace with bits set (1)

`-undef`

replace with undef (x) bits, may be used with `-undriven`

`-anyseq`

replace with \$anyseq drivers (for formal)

`-anyconst`

replace with \$anyconst drivers (for formal)

`-random <seed>`

replace with random bits using the specified integer as seed

(continues on next page)

(continued from previous page)

```

    value for the random number generator.

-init
    also create/update init values for flip-flops

-params
    replace undef in cell parameters

```

G.181 share - perform sat-based resource sharing

```
share [options] [selection]
```

This pass merges shareable resources into a single resource. A SAT solver is used to determine if two resources are share-able.

```
-force
    Per default the selection of cells that is considered for sharing is
    narrowed using a list of cell types. With this option all selected
    cells are considered for resource sharing.

    IMPORTANT NOTE: If the -all option is used then no cells with internal
    state must be selected!

-aggressive
    Per default some heuristics are used to reduce the number of cells
    considered for resource sharing to only large resources. This options
    turns this heuristics off, resulting in much more cells being considered
    for resource sharing.

-fast
    Only consider the simple part of the control logic in SAT solving, resulting
    in much easier SAT problems at the cost of maybe missing some opportunities
    for resource sharing.

-limit N
    Only perform the first N merges, then stop. This is useful for debugging.
```

G.182 shell - enter interactive command mode

```
shell
```

This command enters the interactive command mode. This can be useful in a script to interrupt the script at a certain point and allow for interactive inspection or manual synthesis of the design at this point.

The command prompt of the interactive shell indicates the current selection (see 'help select'):

(continues on next page)

(continued from previous page)

```
yosys>
    the entire design is selected

yosys*>
    only part of the design is selected

yosys [modname]>
    the entire module 'modname' is selected using 'select -module modname'

yosys [modname]*>
    only part of current module 'modname' is selected
```

When in interactive shell, some errors (e.g. invalid command arguments) do not terminate yosys but return to the command prompt.

This command is the default action if nothing else has been specified on the command line.

Press Ctrl-D or type 'exit' to leave the interactive shell.

G.183 show - generate schematics using graphviz

```
show [options] [selection]
```

Create a graphviz DOT file for the selected part of the design and compile it to a graphics file (usually SVG or PostScript).

```
-viewer <viewer>
    Run the specified command with the graphics file as parameter.
    On Windows, this pauses yosys until the viewer exits.
    Use "-viewer none" to not run any command.

-format <format>
    Generate a graphics file in the specified format. Use 'dot' to just
    generate a .dot file, or other <format> strings such as 'svg' or 'ps'
    to generate files in other formats (this calls the 'dot' command).

-lib <verilog_or_rtlil_file>
    Use the specified library file for determining whether cell ports are
    inputs or outputs. This option can be used multiple times to specify
    more than one library.

    note: in most cases it is better to load the library before calling
    show with 'read_verilog -lib <filename>'. it is also possible to
    load liberty files with 'read_liberty -lib <filename>'.

-prefix <prefix>
    generate <prefix>.* instead of ~/.yosys_show.*
```

(continues on next page)

(continued from previous page)

```

-color <color> <object>
    assign the specified color to the specified object. The object can be
    a single selection wildcard expressions or a saved set of objects in
    the @<name> syntax (see "help select" for details).

-label <text> <object>
    assign the specified label text to the specified object. The object can
    be a single selection wildcard expressions or a saved set of objects in
    the @<name> syntax (see "help select" for details).

-colors <seed>
    Randomly assign colors to the wires. The integer argument is the seed
    for the random number generator. Change the seed value if the colored
    graph still is ambiguous. A seed of zero deactivates the coloring.

-colorattr <attribute_name>
    Use the specified attribute to assign colors. A unique color is
    assigned to each unique value of this attribute.

-width
    annotate buses with a label indicating the width of the bus.

-signed
    mark ports (A, B) that are declared as signed (using the [AB]_SIGNED
    cell parameter) with an asterisk next to the port name.

-stretch
    stretch the graph so all inputs are on the left side and all outputs
    (including inout ports) are on the right side.

-pause
    wait for the user to press enter to before returning

-enum
    enumerate objects with internal ($-prefixed) names

-long
    do not abbreviate objects with internal ($-prefixed) names

-notitle
    do not add the module name as graph title to the dot file

-nobg
    don't run viewer in the background, IE wait for the viewer tool to
    exit before returning

```

When no <format> is specified, 'dot' is used. When no <format> and <viewer> is specified, 'xdot' is used to display the schematic (POSIX systems only).

The generated output files are '~/yosys_show.dot' and '~/yosys_show.<format>', unless another prefix is specified using -prefix <prefix>.

(continues on next page)

(continued from previous page)

Yosys on Windows and YosysJS use different defaults: The output is written to 'show.dot' in the current directory and new viewer is launched each time the 'show' command is executed.

G.184 shregmap - map shift registers

```
shregmap [options] [selection]
```

This pass converts chains of `$_DFF_[NP]_` gates to target specific shift register primitives. The generated shift register will be of type `$_SHREG_DFF_[NP]_` and will use the same interface as the original `$_DFF_*_` cells. The cell parameter 'DEPTH' will contain the depth of the shift register. Use a target-specific 'techmap' map file to convert those cells to the actual target cells.

```
-minlen N
    minimum length of shift register (default = 2)
    (this is the length after -keep_before and -keep_after)

-maxlen N
    maximum length of shift register (default = no limit)
    larger chains will be mapped to multiple shift register instances

-keep_before N
    number of DFFs to keep before the shift register (default = 0)

-keep_after N
    number of DFFs to keep after the shift register (default = 0)

-clkpol pos|neg|any
    limit match to only positive or negative edge clocks. (default = any)

-enpol pos|neg|none|any_or_none|any
    limit match to FFs with the specified enable polarity. (default = none)

-match <cell_type>[:<d_port_name>:<q_port_name>]
    match the specified cells instead of $_DFF_N_ and $_DFF_P_. If
    '[:<d_port_name>:<q_port_name>]' is omitted then 'D' and 'Q' is used
    by default. E.g. the option '-clkpol pos' is just an alias for
    '-match $_DFF_P_', which is an alias for '-match $_DFF_P_:D:Q'.

-params
    instead of encoding the clock and enable polarity in the cell name by
    deriving from the original cell name, simply name all generated cells
    $_SHREG_ and use CLKPOL and ENPOL parameters. An ENPOL value of 2 is
    used to denote cells without enable input. The ENPOL parameter is
    omitted when '-enpol none' (or no -enpol option) is passed.

-zinit
```

(continues on next page)

(continued from previous page)

```

assume the shift register is automatically zero-initialized, so it
becomes legal to merge zero initialized FFs into the shift register.

-init
  map initialized registers to the shift reg, add an INIT parameter to
  generated cells with the initialization value. (first bit to shift out
  in LSB position)

-tech greenpak4
  map to greenpak4 shift registers.

```

G.185 sim - simulate the circuit

```
sim [options] [top-level]
```

This command simulates the circuit using the given top-level module.

```

-vcd <filename>
  write the simulation results to the given VCD file

-fst <filename>
  write the simulation results to the given FST file

-aiw <filename>
  write the simulation results to an AIGER witness file
  (requires a *.aim file via -map)

-hdlname
  use the hdlname attribute when writing simulation results
  (preserves hierarchy in a flattened design)

-x
  ignore constant x outputs in simulation file.

-date
  include date and full version info in output.

-clock <portname>
  name of top-level clock input

-clockn <portname>
  name of top-level clock input (inverse polarity)

-multiclock
  mark that witness file is multiclock.

-reset <portname>
  name of top-level reset input (active high)

```

(continues on next page)

(continued from previous page)

```
-resethn <portname>
    name of top-level inverted reset input (active low)

-rstlen <integer>
    number of cycles reset should stay active (default: 1)

-zinit
    zero-initialize all uninitialized regs and memories

-timescale <string>
    include the specified timescale declaration in the vcd

-n <integer>
    number of clock cycles to simulate (default: 20)

-a
    use all nets in VCD/FST operations, not just those with public names

-w
    writeback mode: use final simulation state as new init state

-r <filename>
    read simulation or formal results file
    File formats supported: FST, VCD, AIW, WIT and .yw
    VCD support requires vcd2fst external tool to be present

-append <integer>
    number of extra clock cycles to simulate for a Yosys witness input

-summary <filename>
    write a JSON summary to the given file

-map <filename>
    read file with port and latch symbols, needed for AIGER witness input

-scope <name>
    scope of simulation top model

-at <time>
    sets start and stop time

-start <time>
    start co-simulation in arbitrary time (default 0)

-stop <time>
    stop co-simulation in arbitrary time (default END)

-sim
    simulation with stimulus from FST (default)

-sim-cmp
    co-simulation expect exact match
```

(continues on next page)

(continued from previous page)

```

-sim-gold
    co-simulation, x in simulation can match any value in FST

-sim-gate
    co-simulation, x in FST can match any value in simulation

-q
    disable per-cycle/sample log message

-d
    enable debug output

```

G.186 simplemap - mapping simple coarse-grain cells

```
simplemap [selection]
```

This pass maps a small selection of simple coarse-grain cells to yosys gate primitives. The following internal cell types are mapped by this pass:

```

$not, $pos, $and, $or, $xor, $xnor
$reduce_and, $reduce_or, $reduce_xor, $reduce_xnor, $reduce_bool
$logic_not, $logic_and, $logic_or, $mux, $tribuf
$sr, $ff, $dff, $dffe, $dffsr, $dffsre, $adff, $adffe, $aldff, $aldffe, $sdff,
$sdffe, $sdffce, $dlatch, $adlatch, $dlatchsr

```

G.187 splice - create explicit splicing cells

```
splice [options] [selection]
```

This command adds \$slice and \$concat cells to the design to make the splicing of multi-bit signals explicit. This for example is useful for coarse grain synthesis, where dedicated hardware is needed to splice signals.

```

-sel_by_cell
    only select the cell ports to rewire by the cell. if the selection
    contains a cell, than all cell inputs are rewired, if necessary.

-sel_by_wire
    only select the cell ports to rewire by the wire. if the selection
    contains a wire, than all cell ports driven by this wire are wired,
    if necessary.

-sel_any_bit
    it is sufficient if the driver of any bit of a cell port is selected.
    by default all bits must be selected.

```

(continues on next page)

(continued from previous page)

```
-wires
    also add $slice and $concat cells to drive otherwise unused wires.

-no_outputs
    do not rewire selected module outputs.

-port <name>
    only rewire cell ports with the specified name. can be used multiple
    times. implies -no_output.

-no_port <name>
    do not rewire cell ports with the specified name. can be used multiple
    times. can not be combined with -port <name>.
```

By default selected output wires and all cell ports of selected cells driven by selected wires are rewired.

G.188 splitcells - split up multi-bit cells

```
splitcells [options] [selection]
```

This command splits multi-bit cells into smaller chunks, based on usage of the cell output bits.

This command operates only in cells such as \$or, \$and, and \$mux, that are easily cut into bit-slices.

```
-format char1[char2[char3]]
    the first char is inserted between the cell name and the bit index, the
    second char is appended to the cell name. e.g. -format () creates cell
    names like 'mycell(42)'. the 3rd character is the range separation
    character when creating multi-bit cells. the default is '[]:'.
```

G.189 splitnets - split up multi-bit nets

```
splitnets [options] [selection]
```

This command splits multi-bit nets into single-bit nets.

```
-format char1[char2[char3]]
    the first char is inserted between the net name and the bit index, the
    second char is appended to the netname. e.g. -format () creates net
    names like 'mysignal(42)'. the 3rd character is the range separation
    character when creating multi-bit wires. the default is '[]:'.
```

```
-ports
    also split module ports. per default only internal signals are split.
```

(continues on next page)

(continued from previous page)

```
-driver
    don't blindly split nets in individual bits. instead look at the driver
    and split nets so that no driver drives only part of a net.
```

G.190 sta - perform static timing analysis

```
sta [options] [selection]
```

This command performs static timing analysis on the design. (Only considers paths within a single module, so the design must be flattened.)

G.191 stat - print some statistics

```
stat [options] [selection]
```

Print some statistics (number of objects) on the selected portion of the design.

```
-top <module>
    print design hierarchy with this module as top. if the design is fully
    selected and a module has the 'top' attribute set, this module is used
    default value for this option.

-liberty <liberty_file>
    use cell area information from the provided liberty file

-tech <technology>
    print area estimate for the specified technology. Currently supported
    values for <technology>: xilinx, cmos

-width
    annotate internal cell types with their word width.
    e.g. $add_8 for an 8 bit wide $add cell.

-json
    output the statistics in a machine-readable JSON format.
    this is output to the console; use "tee" to output to a file.
```

G.192 submod - moving part of a module to a new submodule

```
submod [options] [selection]
```

This pass identifies all cells with the 'submod' attribute and moves them to a newly created module. The value of the attribute is used as name for the cell that replaces the group of cells with the same attribute value.

This pass can be used to create a design hierarchy in flat design. This can be useful for analyzing or reverse-engineering a design.

This pass only operates on completely selected modules with no processes or memories.

-copy

by default the cells are 'moved' from the source module and the source module will use an instance of the new module after this command is finished. call with -copy to not modify the source module.

-name <name>

don't use the 'submod' attribute but instead use the selection. only objects from one module might be selected. the value of the -name option is used as the value of the 'submod' attribute instead.

-hidden

instead of creating submodule ports with public names, create ports with private names so that a subsequent 'flatten; clean' call will restore the original module with original public names.

G.193 supercover - add hi/lo cover cells for each wire bit

```
supercover [options] [selection]
```

This command adds two cover cells for each bit of each selected wire, one checking for a hi signal level and one checking for lo level.

G.194 synth - generic synthesis script

```
synth [options]
```

This command runs the default synthesis script. This command does not operate on partly selected designs.

-top <module>

use the specified module as top module (default='top')

-auto-top

automatically determine the top of the design hierarchy

(continues on next page)

(continued from previous page)

```

-flatten
    flatten the design before synthesis. this will pass '-auto-top' to
    'hierarchy' if no top module is specified.

-encfile <file>
    passed to 'fsm_recode' via 'fsm'

-lut <k>
    perform synthesis for a k-LUT architecture.

-nofsm
    do not run FSM optimization

-noabc
    do not run abc (as if yosys was compiled without ABC support)

-noalumacc
    do not run 'alumacc' pass. i.e. keep arithmetic operators in
    their direct form ($add, $sub, etc.).

-nordff
    passed to 'memory'. prohibits merging of FFs into memory read ports

-noshare
    do not run SAT-based resource sharing

-run <from_label>[:<to_label>]
    only run the commands between the labels (see below). an empty
    from label is synonymous to 'begin', and empty to label is
    synonymous to the end of the command list.

-abc9
    use new ABC9 flow (EXPERIMENTAL)

-flowmap
    use FlowMap LUT techmapping instead of ABC

-no-rw-check
    marks all recognized read ports as "return don't-care value on
    read/write collision" (same result as setting the no_rw_check
    attribute on all memories).

```

The following commands are executed by this synthesis command:

```

begin:
    hierarchy -check [-top <top> | -auto-top]

coarse:
    proc
    flatten      (if -flatten)

```

(continues on next page)

G.201 synth_fabulous - FABulous synthesis script

```
synth_fabulous [options]
```

This command runs synthesis for FPGA fabrics generated with FABulous. This command does ↪not operate on partly selected designs.

```
-top <module>
    use the specified module as top module (default='top')

-auto-top
    automatically determine the top of the design hierarchy

-blif <file>
    write the design to the specified BLIF file. writing of an output file
    is omitted if this parameter is not specified.

-edif <file>
    write the design to the specified EDIF file. writing of an output file
    is omitted if this parameter is not specified.

-json <file>
    write the design to the specified JSON file. writing of an output file
    is omitted if this parameter is not specified.

-lut <k>
    perform synthesis for a k-LUT architecture (default 4).

-vpr
    perform synthesis for the FABulous VPR flow (using slightly different ↪
↪techmapping).

-plib <primitive_library.v>
    use the specified Verilog file as a primitive library.

-extra-plib <primitive_library.v>
    use the specified Verilog file for extra primitives (can be specified multiple
    times).

-extra-map <techamp.v>
    use the specified Verilog file for extra techmap rules (can be specified multiple
```

(continues on next page)

(continued from previous page)

```

    times).

-encfile <file>
    passed to 'fsm_recode' via 'fsm'

-nofsm
    do not run FSM optimization

-noalumacc
    do not run 'alumacc' pass. i.e. keep arithmetic operators in
    their direct form ($add, $sub, etc.).

-carry <none|ha>
    carry mapping style (none, half-adders, ...) default=none

-noregfile
    do not map register files

-iopad
    enable automatic insertion of IO buffers (otherwise a wrapper
    with manually inserted and constrained IO should be used.)

-complex-dff
    enable support for FFs with enable and synchronous SR (must also be
    supported by the target fabric.)

-noflatten
    do not flatten design after elaboration

-nordff
    passed to 'memory'. prohibits merging of FFs into memory read ports

-noshare
    do not run SAT-based resource sharing

-run <from_label>[:<to_label>]
    only run the commands between the labels (see below). an empty
    from label is synonymous to 'begin', and empty to label is
    synonymous to the end of the command list.

-no-rw-check
    marks all recognized read ports as "return don't-care value on
    read/write collision" (same result as setting the no_rw_check
    attribute on all memories).
```

The following commands are executed by this synthesis command:

G.202 synth_gatemate - synthesis for Cologne Chip GateMate FPGAs

```
synth_gatemate [options]
```

This command runs synthesis for Cologne Chip AG GateMate FPGAs.

```

-top <module>
    use the specified module as top module.

-vlog <file>
    write the design to the specified verilog file. Writing of an output
    file is omitted if this parameter is not specified.

-json <file>
    write the design to the specified JSON file. Writing of an output file
    is omitted if this parameter is not specified.

-run <from_label>:<to_label>
    only run the commands between the labels (see below). An empty
    from label is synonymous to 'begin', and empty to label is
    synonymous to the end of the command list.

-noflatten
    do not flatten design before synthesis.

-nobram
    do not use CC_BRAM_20K or CC_BRAM_40K cells in output netlist.

-noaddf
    do not use CC_ADDF full adder cells in output netlist.

-nomult
    do not use CC_MULT multiplier cells in output netlist.

```

(continues on next page)

(continued from previous page)

```
-nomx8, -nomx4
    do not use CC_MX{8,4} multiplexer cells in output netlist.

-luttree
    use new LUT tree mapping approach (EXPERIMENTAL).

-dff
    run 'abc' with -dff option

-retime
    run 'abc' with '-dff -D 1' options

-noiopad
    disable I/O buffer insertion (useful for hierarchical or
    out-of-context flows).

-noclkbuf
    disable automatic clock buffer insertion.
```

The following commands are executed by this synthesis command:

G.206 synth_intel - synthesis for Intel (Altera) FPGAs.

```
synth_intel [options]
```

This command runs synthesis for Intel FPGAs.

```
-family <max10 | cyclone10lp | cycloneiv | cycloneive>
    generate the synthesis netlist for the specified family.
    MAX10 is the default target if no family argument specified.
    For Cyclone IV GX devices, use cycloneiv argument; for Cyclone IV E, use
    cycloneive. For Cyclone V and Cyclone 10 GX, use the synth_intel_alm
    backend instead.

-top <module>
    use the specified module as top module (default='top')

-vqm <file>
    write the design to the specified Verilog Quartus Mapping File. Writing
    of an output file is omitted if this parameter is not specified.
    Note that this backend has not been tested and is likely incompatible
    with recent versions of Quartus.

-vpr <file>
    write BLIF files for VPR flow experiments. The synthesized BLIF output
    file is not compatible with the Quartus flow. Writing of an
    output file is omitted if this parameter is not specified.

-run <from_label>:<to_label>
    only run the commands between the labels (see below). an empty
    from label is synonymous to 'begin', and empty to label is
    synonymous to the end of the command list.

-iopads
    use IO pad cells in output netlist

-nobram
    do not use block RAM cells in output netlist

-noflatten
    do not flatten design before synthesis

-retime
    run 'abc' with '-dff -D 1' options
```

The following commands are executed by this synthesis command:

```

WARNING: THE 'synth_intel' COMMAND IS EXPERIMENTAL.

G.207 synth_intel_alm - synthesis for ALM-based Intel (Altera) FPGAs.

```
synth_intel_alm [options]
```

This command runs synthesis for ALM-based Intel FPGAs.

```
-top <module>
    use the specified module as top module

-family <family>
    target one of:
    "cyclonev"      - Cyclone V (default)
    "arriav"        - Arria V (non-GZ)
    "cyclone10gx"   - Cyclone 10GX

-vqm <file>
    write the design to the specified Verilog Quartus Mapping File. Writing
    of an output file is omitted if this parameter is not specified. Implies
    -quartus.

-noflatten
    do not flatten design before synthesis; useful for per-module area
    statistics

-quartus
    output a netlist using Quartus cells instead of MISTRAL_* cells

-dff
    pass DFFs to ABC to perform sequential logic optimisations
    (EXPERIMENTAL)

-run <from_label>:<to_label>
    only run the commands between the labels (see below). an empty
    from label is synonymous to 'begin', and empty to label is
    synonymous to the end of the command list.

-nolutram
    do not use LUT RAM cells in output netlist

-nobram
    do not use block RAM cells in output netlist

-nodsp
    do not map multipliers to MISTRAL_MUL cells

-noiopad
```

(continues on next page)

(continued from previous page)

```

do not instantiate IO buffers

-noclkbuf
do not insert global clock buffers

```

G.212 synth_xilinx - synthesis for Xilinx FPGAs

```
synth_xilinx [options]
```

This command runs synthesis for Xilinx FPGAs. This command does not operate on partly selected designs. At the moment this command creates netlists that are compatible with 7-Series Xilinx devices.

```

-top <module>
    use the specified module as top module

-family <family>
    run synthesis for the specified Xilinx architecture
    generate the synthesis netlist for the specified family.
    supported values:
    - xcup: Ultrascale Plus
    - xcu: Ultrascale
    - xc7: Series 7 (default)
    - xc6s: Spartan 6
    - xc6v: Virtex 6
    - xc5v: Virtex 5 (EXPERIMENTAL)
    - xc4v: Virtex 4 (EXPERIMENTAL)
    - xc3sda: Spartan 3A DSP (EXPERIMENTAL)
    - xc3sa: Spartan 3A (EXPERIMENTAL)
    - xc3se: Spartan 3E (EXPERIMENTAL)
    - xc3s: Spartan 3 (EXPERIMENTAL)
    - xc2vp: Virtex 2 Pro (EXPERIMENTAL)
    - xc2v: Virtex 2 (EXPERIMENTAL)
    - xcve: Virtex E, Spartan 2E (EXPERIMENTAL)
    - xcv: Virtex, Spartan 2 (EXPERIMENTAL)

-edif <file>
    write the design to the specified edif file. writing of an output file
    is omitted if this parameter is not specified.

-blif <file>
    write the design to the specified BLIF file. writing of an output file
    is omitted if this parameter is not specified.

-ise
    generate an output netlist suitable for ISE

```

(continues on next page)

(continued from previous page)

```
-nobram
    do not use block RAM cells in output netlist

-nolutram
    do not use distributed RAM cells in output netlist

-nosrl
    do not use distributed SRL cells in output netlist

-nocarry
    do not use XORCY/MUXCY/CARRY4 cells in output netlist

-nowidelut
    do not use MUXF[5-9] resources to implement LUTs larger than native for
    the target

-nodsp
    do not use DSP48*s to implement multipliers and associated logic

-noiopad
    disable I/O buffer insertion (useful for hierarchical or
    out-of-context flows)

-noclkbuf
    disable automatic clock buffer insertion

-uram
    infer URAM288s for large memories (xcup only)

-widemux <int>
    enable inference of hard multiplexer resources (MUXF[78]) for muxes at
    or above this number of inputs (minimum value 2, recommended value >= 5)
    default: 0 (no inference)

-run <from_label>:<to_label>
    only run the commands between the labels (see below). an empty
    from label is synonymous to 'begin', and empty to label is
    synonymous to the end of the command list.

-flatten
    flatten design before synthesis

-dff
    run 'abc'/'abc9' with -dff option

-retime
    run 'abc' with '-D 1' option to enable flip-flop retiming.
    implies -dff.

-abc9
    use new ABC9 flow (EXPERIMENTAL)
```

```

G.213 synthprop - synthesize SVA properties

```
synthprop [options]
```

This creates synthesizable properties for selected module.

```
-name <portname>
```

Name output port for assertions (default: assertions).

```
-map <filename>
```

Write port mapping for synthesizable properties.

```
-or_outputs
```

Or all outputs together to create a single output that goes high when any property is violated, instead of generating individual output bits.

```
-reset <portname>
```

Name of top-level reset input. Latch a high state on the generated outputs until an asynchronous top-level reset input is activated.

```
-resetn <portname>
```

Name of top-level reset input (inverse polarity). Latch a high state on the generated outputs until an asynchronous top-level reset input is activated.

G.214 tcl - execute a TCL script file

```
tcl <filename> [args]
```

This command executes the tcl commands in the specified file.

Use 'yosys cmd' to run the yosys command 'cmd' from tcl.

The tcl command 'yosys -import' can be used to import all yosys commands directly as tcl commands to the tcl shell. Yosys commands 'proc' and 'rename' are wrapped to tcl commands 'procs' and 'renames' in order to avoid a name collision with the built in commands.

If any arguments are specified, these arguments are provided to the script via the standard \$argc and \$argv variables.

Note, tcl will not receive the output of any yosys command. If the output

(continues on next page)

(continued from previous page)

of the tcl commands are needed, use the yosys command 'tee -s result.string' to redirect yosys's output to the 'result.string' scratchpad value.

G.215 techmap - generic technology mapper

```
techmap [-map filename] [selection]
```

This pass implements a very simple technology mapper that replaces cells in the design with implementations given in form of a Verilog or RTLIL source file.

```
-map filename
    the library of cell implementations to be used.
    without this parameter a builtin library is used that
    transforms the internal RTL cells to the internal gate
    library.

-map %<design-name>
    like -map above, but with an in-memory design instead of a file.

-extern
    load the cell implementations as separate modules into the design
    instead of inlining them.

-max_iter <number>
    only run the specified number of iterations on each module.
    default: unlimited

-recursive
    instead of the iterative breadth-first algorithm use a recursive
    depth-first algorithm. both methods should yield equivalent results,
    but may differ in performance.

-autoproc
    Automatically call "proc" on implementations that contain processes.

-wb
    Ignore the 'whitebox' attribute on cell implementations.

-assert
    this option will cause techmap to exit with an error if it can't map
    a selected cell. only cell types that end on an underscore are accepted
    as final cell types by this mode.

-D <define>, -I <incdir>
    this options are passed as-is to the Verilog frontend for loading the
    map file. Note that the Verilog frontend is also called with the
    '-nooverwrite' option set.
```

(continues on next page)

(continued from previous page)

When a module in the map file has the 'techmap_celltype' attribute set, it will match cells with a type that match the text value of this attribute. Otherwise the module name will be used to match the cell. Multiple space-separated cell types can be listed, and wildcards using [] will be expanded (ie. "\$_DFF_[PN]_" is the same as "\$_DFF_P_ \$_DFF_N_").

When a module in the map file has the 'techmap_simplemap' attribute set, techmap will use 'simplemap' (see 'help simplemap') to map cells matching the module.

When a module in the map file has the 'techmap_maccmap' attribute set, techmap will use 'maccmap' (see 'help maccmap') to map cells matching the module.

When a module in the map file has the 'techmap_wrap' attribute set, techmap will create a wrapper for the cell and then run the command string that the attribute is set to on the wrapper module.

When a port on a module in the map file has the 'techmap_autopurge' attribute set, and that port is not connected in the instantiation that is mapped, then a cell port connected only to such wires will be omitted in the mapped version of the circuit.

All wires in the modules from the map file matching the pattern `_TECHMAP_*` or `*._TECHMAP_*` are special wires that are used to pass instructions from the mapping module to the techmap command. At the moment the following special wires are supported:

`_TECHMAP_FAIL_`

When this wire is set to a non-zero constant value, techmap will not use this module and instead try the next module with a matching 'techmap_celltype' attribute.

When such a wire exists but does not have a constant value after all `_TECHMAP_DO_*` commands have been executed, an error is generated.

`_TECHMAP_DO_*`

This wires are evaluated in alphabetical order. The constant text value of this wire is a yosys command (or sequence of commands) that is run by techmap on the module. A common use case is to run 'proc' on modules that are written using always-statements.

When such a wire has a non-constant value at the time it is to be evaluated, an error is produced. That means it is possible for such a wire to start out as non-constant and evaluate to a constant value during processing of other `_TECHMAP_DO_*` commands.

A `_TECHMAP_DO_*` command may start with the special token 'CONSTMAP; '. in this case techmap will create a copy for each distinct configuration of constant inputs and shorted inputs at this point and import the constant and connected bits into the map module. All further commands are executed in this copy. This is a very convenient way of creating optimized specializations of techmap modules without using the special parameters described below.

(continues on next page)

(continued from previous page)

A `_TECHMAP_DO_*` command may start with the special token `'RECURSION; '`. then techmap will recursively replace the cells in the module with their implementation. This is not affected by the `-max_iter` option.

It is possible to combine both prefixes to `'RECURSION; CONSTMAP; '`.

`_TECHMAP_REMOVEINIT_<port-name>_`

When this wire is set to a constant value, the init attribute of the wire(s) connected to this port will be consumed. This wire must have the same width as the given port, and for every bit that is set to 1 in the value, the corresponding init attribute bit will be changed to 1'bx. If all bits of an init attribute are left as x, it will be removed.

In addition to this special wires, techmap also supports special parameters in modules in the map file:

`_TECHMAP_CELLTYPE_`

When a parameter with this name exists, it will be set to the type name of the cell that matches the module.

`_TECHMAP_CELLNAME_`

When a parameter with this name exists, it will be set to the name of the cell that matches the module.

`_TECHMAP_CONSTMSK_<port-name>_`

`_TECHMAP_CONSTVAL_<port-name>_`

When this pair of parameters is available in a module for a port, then former has a 1-bit for each constant input bit and the latter has the value for this bit. The unused bits of the latter are set to undef (x).

`_TECHMAP_WIREINIT_<port-name>_`

When a parameter with this name exists, it will be set to the initial value of the wire(s) connected to the given port, as specified by the init attribute. If the attribute doesn't exist, x will be filled for the missing bits. To remove the init attribute bits used, use the `_TECHMAP_REMOVEINIT_*_` wires.

`_TECHMAP_BITS_CONNMAP_`

`_TECHMAP_CONNMAP_<port-name>_`

For an N-bit port, the `_TECHMAP_CONNMAP_<port-name>_` parameter, if it exists, will be set to an `N*_TECHMAP_BITS_CONNMAP_` bit vector containing N words (of `_TECHMAP_BITS_CONNMAP_` bits each) that assign each single bit driver a unique id. The values 0-3 are reserved for 0, 1, x, and z. This can be used to detect shorted inputs.

When a module in the map file has a parameter where the according cell in the design has a port, the module from the map file is only used if the port in the design is connected to a constant value. The parameter is then set to the constant value.

A cell with the name `_TECHMAP_REPLACE_` in the map file will inherit the name

(continues on next page)

(continued from previous page)

and attributes of the cell that is being replaced.

A cell with a name of the form ``_TECHMAP_REPLACE_.<suffix>`` in the map file will be named thus but with the ``_TECHMAP_REPLACE_`` prefix substituted with the name of the cell being replaced.

Similarly, a wire named in the form ``_TECHMAP_REPLACE_.<suffix>`` will cause a new wire alias to be created and named as above but with the ``_TECHMAP_REPLACE_`` prefix also substituted.

See 'help extract' for a pass that does the opposite thing.

See 'help flatten' for a pass that does flatten the design (which is essentially techmap but using the design itself as map library).

G.216 tee - redirect command output to file

```
tee [-q] [-o logfile|-a logfile] cmd
```

Execute the specified command, optionally writing the commands output to the specified logfile(s).

```
-q
    Do not print output to the normal destination (console and/or log file).

-o logfile
    Write output to this file, truncate if exists.

-a logfile
    Write output to this file, append if exists.

-s scratchpad
    Write output to this scratchpad value, truncate if it exists.

+INT, -INT
    Add/subtract INT from the -v setting for this command.
```

G.217 test_abcloop - automatically test handling of loops in abc command

```
test_abcloop [options]
```

Test handling of logic loops in ABC.

```
-n {integer}
    create this number of circuits and test them (default = 100).

-s {positive_integer}
    use this value as rng seed value (default = unix time).
```

G.218 test_autotb - generate simple test benches

```
test_autotb [options] [filename]
```

Automatically create primitive Verilog test benches for all modules in the design. The generated testbenches toggle the input pins of the module in a semi-random manner and dumps the resulting output signals.

This can be used to check the synthesis results for simple circuits by comparing the testbench output for the input files and the synthesis results.

The backend automatically detects clock signals. Additionally a signal can be forced to be interpreted as clock signal by setting the attribute 'gentb_clock' on the signal.

The attribute 'gentb_constant' can be used to force a signal to a constant value after initialization. This can e.g. be used to force a reset signal low in order to explore more inner states in a state machine.

The attribute 'gentb_skip' can be attached to modules to suppress testbench generation.

```
-n <int>
    number of iterations the test bench should run (default = 1000)

-seed <int>
    seed used for pseudo-random number generation (default = 0).
    a value of 0 will cause an arbitrary seed to be chosen, based on
    the current system time.
```

G.219 test_cell - automatically test the implementation of a cell type

```
test_cell [options] {cell-types}
```

Tests the internal implementation of the given cell type (for example '\$add') by comparing SAT solver, EVAL and TECHMAP implementations of the cell types..

Run with 'all' instead of a cell type to run the test on all supported cell types. Use for example 'all /\$add' for all cell types except \$add.

```
-n {integer}
    create this number of cell instances and test them (default = 100).

-s {positive_integer}
    use this value as rng seed value (default = unix time).

-f {rtlil_file}
    don't generate circuits. instead load the specified RTLIL file.

-w {filename_prefix}
```

(continues on next page)

(continued from previous page)

```

    don't test anything. just generate the circuits and write them
    to RTLIL files with the specified prefix

-map {filename}
    pass this option to techmap.

-simlib
    use "techmap -D SIMLIB_NOCHECKS -map +/simlib.v -max_iter 2 -autoproc"

-aigmap
    instead of calling "techmap", call "aigmap"

-muxdiv
    when creating test benches with dividers, create an additional mux
    to mask out the division-by-zero case

-script {script_file}
    instead of calling "techmap", call "script {script_file}".

-const
    set some input bits to random constant values

-nosat
    do not check SAT model or run SAT equivalence checking

-noeval
    do not check const-eval models

-edges
    test cell edges db creator against sat-based implementation

-v
    print additional debug information to the console

-vlog {filename}
    create a Verilog test bench to test simlib and write_verilog

```

G.220 test_pmgen - test pass for pmgen

```
test_pmgen -reduce_chain [options] [selection]
```

Demo for recursive pmgen patterns. Map chains of AND/OR/XOR to \$reduce_*.

```
test_pmgen -reduce_tree [options] [selection]
```

Demo for recursive pmgen patterns. Map trees of AND/OR/XOR to \$reduce_*.

(continues on next page)

(continued from previous page)

```
test_pmgen -eqpmux [options] [selection]
```

Demo for recursive pmgen patterns. Optimize EQ/NE/PMUX circuits.

```
test_pmgen -generate [options] <pattern_name>
```

Create modules that match the specified pattern.

G.221 torder - print cells in topological order

```
torder [options] [selection]
```

This command prints the selected cells in topological order.

```
-stop <cell_type> <cell_port>
```

do not use the specified cell port in topological sorting

```
-noautostop
```

by default Q outputs of internal FF cells and memory read port outputs are not used in topological sorting. this option deactivates that.

G.222 trace - redirect command output to file

```
trace cmd
```

Execute the specified command, logging all changes the command performs on the design in real time.

G.223 tribuf - infer tri-state buffers

```
tribuf [options] [selection]
```

This pass transforms \$mux cells with 'z' inputs to tristate buffers.

```
-merge
```

merge multiple tri-state buffers driving the same net into a single buffer.

```
-logic
```

convert tri-state buffers that do not drive output ports to non-tristate logic. this option implies -merge.

```
-formal
```

convert all tri-state buffers to non-tristate logic and

(continues on next page)

(continued from previous page)

```
add a formal assertion that no two buffers are driving the
same net simultaneously. this option implies -merge.
```

G.224 uniquify - create unique copies of modules

```
uniquify [selection]
```

By default, a module that is instantiated by several other modules is only kept once in the design. This preserves the original modularity of the design and reduces the overall size of the design in memory. But it prevents certain optimizations and other operations on the design. This pass creates unique modules for all selected cells. The created modules are marked with the 'unique' attribute.

This commands only operates on modules that by themselves have the 'unique' attribute set (the 'top' module is unique implicitly).

G.225 verifc - load Verilog and VHDL designs using Verific

```
verific {-vlog95|-vlog2k|-sv2005|-sv2009|-sv2012|-sv} <verilog-file>..
```

Load the specified Verilog/SystemVerilog files into Verific.

All files specified in one call to this command are one compilation unit. Files passed to different calls to this command are treated as belonging to different compilation units.

Additional -D<macro>[=<value>] options may be added after the option indicating the language version (and before file names) to set additional verilog defines. The macros YOSYS, SYNTHESIS, and VERIFIC are defined implicitly.

```
verific -formal <verilog-file>..
```

Like -sv, but define FORMAL instead of SYNTHESIS.

```
verific {-f|-F} [-vlog95|-vlog2k|-sv2005|-sv2009|
               -sv2012|-sv|-formal] <command-file>
```

Load and execute the specified command file.

Override verilog parsing mode can be set.

The macros YOSYS, SYNTHESIS/FORMAL, and VERIFIC are defined implicitly.

Command file parser supports following commands in file:

```
+define+<MACRO>=<VALUE> - defines macro
-u                        - upper case all identifier (makes Verilog parser
```

(continues on next page)

(continued from previous page)

```

                                case insensitive)
-v <filepath>                  - register library name (file)
-y <filepath>                  - register library name (directory)
+incdir+<filepath>             - specify include dir
+libext+<filepath>             - specify library extension
+liborder+<id>                 - add library in ordered list
+librescan                     - unresolved modules will be always searched
                                starting with the first library specified
                                by -y/-v options.
-f/-file <filepath>            - nested -f option
-F <filepath>                  - nested -F option (relative path)
parse files:
    <filepath>
    +systemverilogext+<filepath>
    +verilog1995ext+<filepath>
    +verilog2001ext+<filepath>

analysis mode:
    -ams
    +v2k
    -sverilog

```

```
verific [-work <libname>] {-sv|-vhdl|...} <hdl-file>
```

Load the specified Verilog/SystemVerilog/VHDL file into the specified library.
(default library when -work is not present: "work")

```
verific [-L <libname>] {-sv|-vhdl|...} <hdl-file>
```

Look up external definitions in the specified library.
(-L may be used more than once)

```
verific -vlog-incdir <directory>..
```

Add Verilog include directories.

```
verific -vlog-libdir <directory>..
```

Add Verilog library directories. Verific will search in this directories to
find undefined modules.

```
verific -vlog-libext <extension>..
```

Add Verilog library extensions, used when searching in library directories.

```
verific -vlog-define <macro>[=<value>]..
```

(continues on next page)

(continued from previous page)

Add Verilog defines.

```
verific -vlog-undef <macro>..
```

Remove Verilog defines previously set with -vlog-define.

```
verific -set-error <msg_id>..  
verific -set-warning <msg_id>..  
verific -set-info <msg_id>..  
verific -set-ignore <msg_id>..
```

Set message severity. <msg_id> is the string in square brackets when a message is printed, such as VERI-1209.

Also errors, warnings, infos and comments could be used to set new severity for all messages of certain type.

```
verific -import [options] <top>..
```

Elaborate the design for the specified top modules or configurations, import to Yosys and reset the internal state of Verific.

Import options:

-all

Elaborate all modules, not just the hierarchy below the given top modules. With this option the list of modules to import is optional.

-gates

Create a gate-level netlist.

-flatten

Flatten the design in Verific before importing.

-extnets

Resolve references to external nets by adding module ports as needed.

-autocover

Generate automatic cover statements for all asserts

-fullinit

Keep all register initializations, even those for non-FF registers.

-cells

Import all cell definitions from Verific loaded libraries even if they are unused in design. Useful with "-edif" and "-liberty" option.

-chparam name value

Elaborate the specified top modules (all modules when -all given) using

(continues on next page)

(continued from previous page)

this parameter value. Modules on which this parameter does not exist will cause Verific to produce a VERI-1928 or VHDL-1676 message. This option can be specified multiple times to override multiple parameters. String values must be passed in double quotes (").

`-v, -vv`

Verbose log messages. (`-vv` is even more verbose than `-v`.)

`-pp <filename>`

Pretty print design after elaboration to specified file.

The following additional import options are useful for debugging the Verific bindings (for Yosys and/or Verific developers):

`-k`

Keep going after an unsupported verific primitive is found. The unsupported primitive is added as blockbox module to the design. This will also add all SVA related cells to the design parallel to the checker logic inferred by it.

`-V`

Import Verific netlist as-is without translating to Yosys cell types.

`-nosva`

Ignore SVA properties, do not infer checker logic.

`-L <int>`

Maximum number of ctrl bits for SVA checker FSMs (default=16).

`-n`

Keep all Verific names on instances and nets. By default only user-declared names are preserved.

`-d <dump_file>`

Dump the Verific netlist as a verilog file.

```
verific [-work <libname>] -pp [options] <filename> [<module>]..
```

Pretty print design (or just module) to the specified file from the specified library. (default library when `-work` is not present: "work")

Pretty print options:

`-verilog`

Save output for Verilog/SystemVerilog design modules (default).

`-vhdl`

Save output for VHDL design units.

```
verific -cfg [<name> [<value>]]
```

(continues on next page)

(continued from previous page)

Get/set Verific runtime flags.

Use YosysHQ Tabby CAD Suite if you need Yosys+Verific.
<https://www.yosyshq.com/>

Contact office@yosyshq.com for free evaluation
binaries of YosysHQ Tabby CAD Suite.

G.226 verilog_defaults - set default options for read_verilog

```
verilog_defaults -add [options]
```

Add the specified options to the list of default options to read_verilog.

```
verilog_defaults -clear
```

Clear the list of Verilog default options.

```
verilog_defaults -push  
verilog_defaults -pop
```

Push or pop the list of default options to a stack. Note that -push does not imply -clear.

G.227 verilog_defines - define and undefine verilog defines

```
verilog_defines [options]
```

Define and undefine verilog preprocessor macros.

```
-Dname[=definition]  
    define the preprocessor symbol 'name' and set its optional value  
    'definition'
```

```
-Uname[=definition]  
    undefine the preprocessor symbol 'name'
```

```
-reset  
    clear list of defined preprocessor symbols
```

```
-list  
    list currently defined preprocessor symbols
```

G.228 viz - visualize data flow graph

```
viz [options] [selection]
```

Create a graphviz DOT file for the selected part of the design, showing the relationships between the selected wires, and compile it to a graphics file (usually SVG or PostScript).

```
-viewer <viewer>
```

Run the specified command with the graphics file as parameter.

On Windows, this pauses yosys until the viewer exits.

```
-format <format>
```

Generate a graphics file in the specified format. Use 'dot' to just generate a .dot file, or other <format> strings such as 'svg' or 'ps' to generate files in other formats (this calls the 'dot' command).

```
-prefix <prefix>
```

generate <prefix>.* instead of ~/.yosys_viz.*

```
-pause
```

wait for the user to press enter to before returning

```
-nobg
```

don't run viewer in the background, IE wait for the viewer tool to exit before returning

```
-set-vg-attr
```

set their group index as 'vg' attribute on cells and wires

```
-g <selection>
```

manually define a group of terminal signals. this group is not being merged with other terminal groups.

```
-u <selection>
```

manually define a unique group for each wire in the selection.

```
-x <selection>
```

manually exclude wires from being considered. (usually this is used for global signals, such as reset.)

```
-s <selection>
```

like -g, but mark group as 'special', changing the algorithm to preserve as much info about this groups connectivity as possible.

```
-G <selection_expr> .
```

```
-U <selection_expr> .
```

```
-X <selection_expr> .
```

```
-S <selection_expr> .
```

like -u, -g, -x, and -s, but parse all arguments up to a terminating . as a single select expression. (see 'help select' for details)

(continues on next page)

(continued from previous page)

```
-0, -1, -2, -3, -4, -5, -6, -7, -8, -9
  select effort level. each level corresponds to an increasingly more
  aggressive sequence of strategies for merging nodes of the data flow
  graph. (default: 9)
```

When no <format> is specified, 'dot' is used. When no <format> and <viewer> is specified, 'xdot' is used to display the schematic (POSIX systems only).

The generated output files are '~/yosys_viz.dot' and '~/yosys_viz.<format>', unless another prefix is specified using -prefix <prefix>.

Yosys on Windows and YosysJS use different defaults: The output is written to 'show.dot' in the current directory and new viewer is launched each time the 'show' command is executed.

G.229 wbfliP - flip the whitebox attribute

```
wbfliP [selection]
```

Flip the whitebox attribute on selected cells. I.e. if it's set, unset it, and vice-versa. Blackbox cells are not effected by this command.

G.230 wreduce - reduce the word size of operations if possible

```
wreduce [options] [selection]
```

This command reduces the word size of operations. For example it will replace the 32 bit adders in the following code with adders of more appropriate widths:

```
module test(input [3:0] a, b, c, output [7:0] y);
  assign y = a + b + c + 1;
endmodule
```

Options:

```
-memx
  Do not change the width of memory address ports. Use this options in
  flows that use the 'memory_memx' pass.

-mux_undef
  remove 'undef' inputs from $mux, $pmux and $_MUX_ cells

-keepdc
  Do not optimize explicit don't-care values.
```

G.231 write_aiger - write design to AIGER file

```
write_aiger [options] [filename]
```

Write the current design to an AIGER file. The design must be flattened and must not contain any cell types except `$_AND_`, `$_NOT_`, simple FF types, `$assert` and `$assume` cells, and `$initstate` cells.

`$assert` and `$assume` cells are converted to AIGER bad state properties and invariant constraints.

```
-ascii
    write ASCII version of AIGER format

-zinit
    convert FFs to zero-initialized FFs, adding additional inputs for
    uninitialized FFs.

-miter
    design outputs are AIGER bad state properties

-symbols
    include a symbol table in the generated AIGER file

-map <filename>
    write an extra file with port and latch symbols

-vmap <filename>
    like -map, but more verbose

-no-startoffset
    make indexes zero based, enable using map files with smt solvers.

-ywmap <filename>
    write a map file for conversion to and from yosys witness traces.

-I, -O, -B, -L
    If the design contains no input/output/assert/flip-flop then create one
    dummy input/output/bad_state-pin or latch to make the tools reading the
    AIGER file happy.
```

G.232 write_blif - write design to BLIF file

```
write_blif [options] [filename]
```

Write the current design to an BLIF file.

```
-top top_module
    set the specified module as design top module
```

(continues on next page)

(continued from previous page)

```

-buf <cell-type> <in-port> <out-port>
    use cells of type <cell-type> with the specified port names for buffers

-unbuf <cell-type> <in-port> <out-port>
    replace buffer cells with the specified name and port names with
    a .names statement that models a buffer

-true <cell-type> <out-port>
-false <cell-type> <out-port>
-undef <cell-type> <out-port>
    use the specified cell types to drive nets that are constant 1, 0, or
    undefined. when '-' is used as <cell-type>, then <out-port> specifies
    the wire name to be used for the constant signal and no cell driving
    that wire is generated. when '+' is used as <cell-type>, then <out-port>
    specifies the wire name to be used for the constant signal and a .names
    statement is generated to drive the wire.

-noalias
    if a net name is aliasing another net name, then by default a net
    without fanout is created that is driven by the other net. This option
    suppresses the generation of this nets without fanout.

```

The following options can be useful when the generated file is not going to be read by a BLIF parser but a custom tool. It is recommended not to name the output file *.blif when any of these options are used.

```

-icells
    do not translate Yosys's internal gates to generic BLIF logic
    functions. Instead create .subckt or .gate lines for all cells.

-gates
    print .gate instead of .subckt lines for all cells that are not
    instantiations of other modules from this design.

-conn
    do not generate buffers for connected wires. instead use the
    non-standard .conn statement.

-attr
    use the non-standard .attr statement to write cell attributes

-param
    use the non-standard .param statement to write cell parameters

-cname
    use the non-standard .cname statement to write cell names

-iname, -iattr
    enable -cname and -attr functionality for .names statements
    (the .cname and .attr statements will be included in the BLIF
    output after the truth table for the .names statement)

```

(continues on next page)

(continued from previous page)

```
-blackbox
    write blackbox cells with .blackbox statement.

-impltf
    do not write definitions for the $true, $false and $undef wires.
```

G.233 write_btor - write design to BTOR file

```
write_btor [options] [filename]
```

Write a BTOR description of the current design.

```
-v
    Add comments and indentation to BTOR output file

-s
    Output only a single bad property for all asserts

-c
    Output cover properties using 'bad' statements instead of asserts

-i <filename>
    Create additional info file with auxiliary information

-x
    Output symbols for internal netnames (starting with '$')

-ywmap <filename>
    Create a map file for conversion to and from Yosys witness traces
```

G.234 write_cxxrtl - convert design to C++ RTL simulation

```
write_cxxrtl [options] [filename]
```

Write C++ code that simulates the design. The generated code requires a driver that instantiates the design, toggles its clock, and interacts with its ports.

The following driver may be used as an example for a design with a single clock driving rising edge triggered flip-flops:

```
#include "top.cc"

int main() {
    cxxrtl_design::p_top top;
    top.step();
    while (1) {
        /* user logic */
    }
}
```

(continues on next page)

(continued from previous page)

```

        top.p_clk.set(false);
        top.step();
        top.p_clk.set(true);
        top.step();
    }
}

```

Note that CXXRTL simulations, just like the hardware they are simulating, are subject to race conditions. If, in the example above, the user logic would run simultaneously with the rising edge of the clock, the design would malfunction.

This backend supports replacing parts of the design with black boxes implemented in C++. If a module marked as a CXXRTL black box, its implementation is ignored, and the generated code consists only of an interface and a factory function. The driver must implement the factory function that creates an implementation of the black box, taking into account the parameters it is instantiated with.

For example, the following Verilog code defines a CXXRTL black box interface for a synchronous debug sink:

```

(* cxxrtl_blackbox *)
module debug(...);
    (* cxxrtl_edge = "p" *) input clk;
    input en;
    input [7:0] i_data;
    (* cxxrtl_sync *) output [7:0] o_data;
endmodule

```

For this HDL interface, this backend will generate the following C++ interface:

```

struct bb_p_debug : public module {
    value<1> p_clk;
    bool posedge_p_clk() const { /* ... */ }
    value<1> p_en;
    value<8> p_i_data;
    wire<8> p_o_data;

    bool eval() override;
    bool commit() override;

    static std::unique_ptr<bb_p_debug>
    create(std::string name, metadata_map parameters, metadata_map attributes);
};

```

The `'create'` function must be implemented by the driver. For example, it could always provide an implementation logging the values to standard error stream:

```

namespace cxxrtl_design {

struct stderr_debug : public bb_p_debug {
    bool eval() override {
        if (posedge_p_clk() && p_en)

```

(continues on next page)

(continued from previous page)

```

        fprintf(stderr, "debug: %02x\n", p_i_data.data[0]);
        p_o_data.next = p_i_data;
        return bb_p_debug::eval();
    }
};

std::unique_ptr<bb_p_debug>
bb_p_debug::create(std::string name, cxxrtl::metadata_map parameters,
                  cxxrtl::metadata_map attributes) {
    return std::make_unique<stderr_debug>();
}

}

```

For complex applications of black boxes, it is possible to parameterize their port widths. For example, the following Verilog code defines a CXXRTL black box interface for a configurable width debug sink:

```

(* cxxrtl_blackbox, cxxrtl_template = "WIDTH" *)
module debug(...);
    parameter WIDTH = 8;
    (* cxxrtl_edge = "p" *) input clk;
    input en;
    (* cxxrtl_width = "WIDTH" *) input [WIDTH - 1:0] i_data;
    (* cxxrtl_width = "WIDTH" *) output [WIDTH - 1:0] o_data;
endmodule

```

For this parametric HDL interface, this backend will generate the following C++ interface (only the differences are shown):

```

template<size_t WIDTH>
struct bb_p_debug : public module {
    // ...
    value<WIDTH> p_i_data;
    wire<WIDTH> p_o_data;
    // ...
    static std::unique_ptr<bb_p_debug<WIDTH>>
        create(std::string name, metadata_map parameters, metadata_map attributes);
};

```

The `'create'` function must be implemented by the driver, specialized for every possible combination of template parameters. (Specialization is necessary to enable separate compilation of generated code and black box implementations.)

```

template<size_t SIZE>
struct stderr_debug : public bb_p_debug<SIZE> {
    // ...
};

template<>
std::unique_ptr<bb_p_debug<8>>
bb_p_debug<8>::create(std::string name, cxxrtl::metadata_map parameters,

```

(continues on next page)

(continued from previous page)

```

        cxrtl::metadata_map attributes) {
    return std::make_unique<stderr_debug<8>>();
}

```

The following attributes are recognized by this backend:

`cxrtl_blackbox`

only valid on modules. if specified, the module contents are ignored, and the generated code includes only the module interface and a factory function, which will be called to instantiate the module.

`cxrtl_edge`

only valid on inputs of black boxes. must be one of "p", "n", "a". if specified on signal ``clk``, the generated code includes edge detectors ``posedge_p_clk()`` (if "p"), ``negedge_p_clk()`` (if "n"), or both (if "a"), simplifying implementation of clocked black boxes.

`cxrtl_template`

only valid on black boxes. must contain a space separated sequence of identifiers that have a corresponding black box parameters. for each of them, the generated code includes a ``size_t`` template parameter.

`cxrtl_width`

only valid on ports of black boxes. must be a constant expression, which is directly inserted into generated code.

`cxrtl_comb, cxrtl_sync`

only valid on outputs of black boxes. if specified, indicates that every bit of the output port is driven, correspondingly, by combinatorial or synchronous logic. this knowledge is used for scheduling optimizations. if neither is specified, the output will be pessimistically treated as driven by both combinatorial and synchronous logic.

The following options are supported by this backend:

`-print-wire-types, -print-debug-wire-types`

enable additional debug logging, for pass developers.

`-header`

generate separate interface (.h) and implementation (.cc) files. if specified, the backend must be called with a filename, and filename of the interface is derived from filename of the implementation. otherwise, interface and implementation are generated together.

`-namespace <ns-name>`

place the generated code into namespace `<ns-name>`. if not specified, "cxrtl_design" is used.

`-nohierarchy`

use design hierarchy as-is. in most designs, a top module should be present as it is exposed through the C API and has unbuffered outputs for improved performance; it will be determined automatically if absent.

(continues on next page)

(continued from previous page)

-noflatten
don't flatten the design. fully flattened designs can evaluate within one delta cycle if they have no combinatorial feedback.
note that the debug interface and waveform dumps use full hierarchical names for all wires even in flattened designs.

-nopro
don't convert processes to netlists. in most designs, converting processes significantly improves evaluation performance at the cost of slight increase in compilation time.

-O <level>
set the optimization level. the default is -O6. higher optimization levels dramatically decrease compile and run time, and highest level possible for a design should be used.

-O0
no optimization.

-O1
unbuffer internal wires if possible.

-O2
like -O1, and localize internal wires if possible.

-O3
like -O2, and inline internal wires if possible.

-O4
like -O3, and unbuffer public wires not marked (*keep*) if possible.

-O5
like -O4, and localize public wires not marked (*keep*) if possible.

-O6
like -O5, and inline public wires not marked (*keep*) if possible.

-g <level>
set the debug level. the default is -g4. higher debug levels provide more visibility and generate more code, but do not pessimize evaluation.

-g0
no debug information. the C API is disabled.

-g1
include bare minimum of debug information necessary to access all design state. the C API is enabled.

-g2
like -g1, but include debug information for all public wires that are directly accessible through the C++ interface.

(continues on next page)

(continued from previous page)

- g3
like -g2, and include debug information for public wires that are tied to a constant or another public wire.
- g4
like -g3, and compute debug information on demand for all public wires that were optimized out.

G.235 write_edif - write design to EDIF netlist file

```
write_edif [options] [filename]
```

Write the current design to an EDIF netlist file.

- top top_module
set the specified module as design top module
- nogndvcc
do not create "GND" and "VCC" cells. (this will produce an error if the design contains constant nets. use "hilomap" to map to custom constant drivers first)
- gndvccy
create "GND" and "VCC" cells with "Y" outputs. (the default is "G" for "GND" and "P" for "VCC".)
- attrprop
create EDIF properties for cell attributes
- keep
create extra KEEP nets by allowing a cell to drive multiple nets.
- pvector {par|bra|ang}
sets the delimiting character for module port rename clauses to parentheses, square brackets, or angle brackets.
- lsbidx
use index 0 for the LSB bit of a net or port instead of MSB.

Unfortunately there are different "flavors" of the EDIF file format. This command generates EDIF files for the Xilinx place&route tools. It might be necessary to make small modifications to this command when a different tool is targeted.

G.236 write_file - write a text to a file

```
write_file [options] output_file [input_file]
```

Write the text from the input file to the output file.

```
-a
    Append to output file (instead of overwriting)
```

Inside a script the input file can also can a here-document:

```
write_file hello.txt <<EOT
Hello World!
EOT
```

G.237 write_firrtl - write design to a FIRRTL file

```
write_firrtl [options] [filename]
```

Write a FIRRTL netlist of the current design.

The following commands are executed by this command:

```
pmuxtree
bmuxmap
demuxmap
bwmuxmap
```

G.238 write_ilang - (deprecated) alias of write_rtlil

See ``help write_rtlil``.

G.239 write_intersynth - write design to InterSynth netlist file

```
write_intersynth [options] [filename]
```

Write the current design to an 'intersynth' netlist file. InterSynth is a tool for Coarse-Grain Example-Driven Interconnect Synthesis.

```
-notypes
    do not generate celltypes and conntypes commands. i.e. just output
    the netlists. this is used for postsilicon synthesis.

-lib <verilog_or_rtlil_file>
    Use the specified library file for determining whether cell ports are
    inputs or outputs. This option can be used multiple times to specify
```

(continues on next page)

(continued from previous page)

```

    more than one library.

-selected
    only write selected modules. modules must be selected entirely or
    not at all.

http://bygone.clairexen.net/intersynth/

```

G.240 write_jny - generate design metadata

```

    jny [options] [selection]

```

Write JSON netlist metadata for the current design

```

    -no-connections
        Don't include connection information in the netlist output.

    -no-attributes
        Don't include attributed information in the netlist output.

    -no-properties
        Don't include property information in the netlist output.

```

The JSON schema for JNY output files is located in the "jny.schema.json" file which is located at "<https://raw.githubusercontent.com/YosysHQ/yosys/master/misc/jny.schema.json>"

G.241 write_json - write design to a JSON file

```

    write_json [options] [filename]

```

Write a JSON netlist of the current design.

```

    -aig
        include AIG models for the different gate types

    -compat-int
        emit 32-bit or smaller fully-defined parameter values directly
        as JSON numbers (for compatibility with old parsers)

```

The general syntax of the JSON output created by this command is as follows:

```

{
  "creator": "Yosys <version info>",
  "modules": {
    <module_name>: {

```

(continues on next page)

(continued from previous page)

```

    "attributes": {
      <attribute_name>: <attribute_value>,
      ...
    },
    "parameter_default_values": {
      <parameter_name>: <parameter_value>,
      ...
    },
    "ports": {
      <port_name>: <port_details>,
      ...
    },
    "cells": {
      <cell_name>: <cell_details>,
      ...
    },
    "memories": {
      <memory_name>: <memory_details>,
      ...
    },
    "netnames": {
      <net_name>: <net_details>,
      ...
    }
  },
  "models": {
    ...
  },
}

```

Where <port_details> is:

```

{
  "direction": <"input" | "output" | "inout">,
  "bits": <bit_vector>
  "offset": <the lowest bit index in use, if non-0>
  "upto": <1 if the port bit indexing is MSB-first>
  "signed": <1 if the port is signed>
}

```

The "offset" and "upto" fields are skipped if their value would be 0. They don't affect connection semantics, and are only used to preserve original HDL bit indexing. And <cell_details> is:

```

{
  "hide_name": <1 | 0>,
  "type": <cell_type>,
  "model": <AIG model name, if -aig option used>,
  "parameters": {
    <parameter_name>: <parameter_value>,
    ...
  }
}

```

(continues on next page)

(continued from previous page)

```

    },
    "attributes": {
        <attribute_name>: <attribute_value>,
        ...
    },
    "port_directions": {
        <port_name>: <"input" | "output" | "inout">,
        ...
    },
    "connections": {
        <port_name>: <bit_vector>,
        ...
    },
}

```

And <memory_details> is:

```

{
    "hide_name": <1 | 0>,
    "attributes": {
        <attribute_name>: <attribute_value>,
        ...
    },
    "width": <memory width>
    "start_offset": <the lowest valid memory address>
    "size": <memory size>
}

```

And <net_details> is:

```

{
    "hide_name": <1 | 0>,
    "bits": <bit_vector>
    "offset": <the lowest bit index in use, if non-0>
    "upto": <1 if the port bit indexing is MSB-first>
    "signed": <1 if the port is signed>
}

```

The "hide_name" fields are set to 1 when the name of this cell or net is automatically created and is likely not of interest for a regular user.

The "port_directions" section is only included for cells for which the interface is known.

Module and cell ports and nets can be single bit wide or vectors of multiple bits. Each individual signal bit is assigned a unique integer. The <bit_vector> values referenced above are vectors of this integers. Signal bits that are connected to a constant driver are denoted as string "0", "1", "x", or "z" instead of a number.

Bit vectors (including integers) are written as string holding the binary representation of the value. Strings are written as strings, with an appended

(continues on next page)

(continued from previous page)

blank in cases of strings of the form `/[01xz]* */`.

For example the following Verilog code:

```
module test(input x, y);
  (* keep *) foo #(.P(42), .Q(1337))
    foo_inst (.A({x, y}), .B({y, x}), .C({4'd10, {4{x}}}));
endmodule
```

Translates to the following JSON output:

```
{
  "creator": "Yosys 0.9+2406 (git sha1 fb1168d8, clang 9.0.1 -fPIC -Os)",
  "modules": {
    "test": {
      "attributes": {
        "cells_not_processed": "00000000000000000000000000000001",
        "src": "test.v:1.1-4.10"
      },
      "ports": {
        "x": {
          "direction": "input",
          "bits": [ 2 ]
        },
        "y": {
          "direction": "input",
          "bits": [ 3 ]
        }
      },
      "cells": {
        "foo_inst": {
          "hide_name": 0,
          "type": "foo",
          "parameters": {
            "P": "0000000000000000000000000000101010",
            "Q": "00000000000000000000000010100111001"
          },
          "attributes": {
            "keep": "0000000000000000000000000000000001",
            "module_not_derived": "00000000000000000000000000000001",
            "src": "test.v:3.1-3.55"
          },
          "connections": {
            "A": [ 3, 2 ],
            "B": [ 2, 3 ],
            "C": [ 2, 2, 2, 2, "0", "1", "0", "1" ]
          }
        }
      },
      "netnames": {
        "x": {
          "hide_name": 0,
```

(continues on next page)

(continued from previous page)

```
    "bits": [ 2 ],
    "attributes": {
        "src": "test.v:1.19-1.20"
    }
},
"y": {
    "hide_name": 0,
    "bits": [ 3 ],
    "attributes": {
        "src": "test.v:1.22-1.23"
    }
}
}
}
}
}
```

The models are given as And-Inverter-Graphs (AIGs) in the following form:

```
"models": {
  <model_name>: [
    /* 0 */ [ <node-spec> ],
    /* 1 */ [ <node-spec> ],
    /* 2 */ [ <node-spec> ],
    ...
  ],
  ...
},
```

The following node-types may be used:

```
[ "port", <portname>, <bitindex>, <out-list> ]
- the value of the specified input port bit

[ "nport", <portname>, <bitindex>, <out-list> ]
- the inverted value of the specified input port bit

[ "and", <node-index>, <node-index>, <out-list> ]
- the ANDed value of the specified nodes

[ "nand", <node-index>, <node-index>, <out-list> ]
- the inverted ANDed value of the specified nodes

[ "true", <out-list> ]
- the constant value 1

[ "false", <out-list> ]
- the constant value 0
```

All nodes appear in topological order. I.e. only nodes with smaller indices are referenced by "and" and "nand" nodes.

(continues on next page)

(continued from previous page)

The optional <out-list> at the end of a node specification is a list of output portname and bitindex pairs, specifying the outputs driven by this node.

For example, the following is the model for a 3-input 3-output \$reduce_and cell inferred by the following code:

```
module test(input [2:0] in, output [2:0] out);
    assign in = &out;
endmodule

"$reduce_and:3U:3": [
    /* 0 */ [ "port", "A", 0 ],
    /* 1 */ [ "port", "A", 1 ],
    /* 2 */ [ "and", 0, 1 ],
    /* 3 */ [ "port", "A", 2 ],
    /* 4 */ [ "and", 2, 3, "Y", 0 ],
    /* 5 */ [ "false", "Y", 1, "Y", 2 ]
]
```

Future version of Yosys might add support for additional fields in the JSON format. A program processing this format must ignore all unknown fields.

G.242 write_rtlil - write design to RTLIL file

```
write_rtlil [filename]
```

Write the current design to an RTLIL file. (RTLIL is a text representation of a design in yosys's internal format.)

```
-selected
    only write selected parts of the design.
```

G.243 write_simplec - convert design to simple C code

```
write_simplec [options] [filename]
```

Write simple C code for simulating the design. The C code written can be used to simulate the design in a C environment, but the purpose of this command is to generate code that works well with C-based formal verification.

```
-verbose
    this will print the recursive walk used to export the modules.

-i8, -i16, -i32, -i64
    set the maximum integer bit width to use in the generated code.
```

THIS COMMAND IS UNDER CONSTRUCTION

G.244 write_smt2 - write design to SMT-LIBv2 file

```
write_smt2 [options] [filename]
```

Write a SMT-LIBv2 [1] description of the current design. For a module with name '<mod>' this will declare the sort '<mod>_s' (state of the module) and will define and declare functions operating on that state.

The following SMT2 functions are generated for a module with name '<mod>'. Some declarations/definitions are printed with a special comment. A prover using the SMT2 files can use those comments to collect all relevant metadata about the design.

```
; yosys-smt2-module <mod>
(declare-sort |<mod>_s| 0)
  The sort representing a state of module <mod>.

(define-fun |<mod>_h| ((state |<mod>_s|)) Bool (...))
  This function must be asserted for each state to establish the
  design hierarchy.

; yosys-smt2-input <wirename> <width>
; yosys-smt2-output <wirename> <width>
; yosys-smt2-register <wirename> <width>
; yosys-smt2-wire <wirename> <width>
(define-fun |<mod>_n <wirename>| (|<mod>_s|) (_ BitVec <width>))
(define-fun |<mod>_n <wirename>| (|<mod>_s|) Bool)
  For each port, register, and wire with the 'keep' attribute set an
  accessor function is generated. Single-bit wires are returned as Bool,
  multi-bit wires as BitVec.

; yosys-smt2-cell <submod> <instancename>
(declare-fun |<mod>_h <instancename>| (|<mod>_s|) |<submod>_s|)
  There is a function like that for each hierarchical instance. It
  returns the sort that represents the state of the sub-module that
  implements the instance.

(declare-fun |<mod>_is| (|<mod>_s|) Bool)
  This function must be asserted 'true' for initial states, and 'false'
  otherwise.

(define-fun |<mod>_i| ((state |<mod>_s|)) Bool (...))
  This function must be asserted 'true' for initial states. For
  non-initial states it must be left unconstrained.

(define-fun |<mod>_t| ((state |<mod>_s|) (next_state |<mod>_s|)) Bool (...))
  This function evaluates to 'true' if the states 'state' and
  'next_state' form a valid state transition.

(define-fun |<mod>_a| ((state |<mod>_s|)) Bool (...))
  This function evaluates to 'true' if all assertions hold in the state.
```

(continues on next page)

(continued from previous page)

```
(define-fun |<mod>_u| ((state |<mod>_s|)) Bool (...))
  This function evaluates to 'true' if all assumptions hold in the state.

; yosys-smt2-assert <id> <filename:linenum>
(define-fun |<mod>_a <id>| ((state |<mod>_s|)) Bool (...))
  Each $assert cell is converted into one of this functions. The function
  evaluates to 'true' if the assert statement holds in the state.

; yosys-smt2-assume <id> <filename:linenum>
(define-fun |<mod>_u <id>| ((state |<mod>_s|)) Bool (...))
  Each $assume cell is converted into one of this functions. The function
  evaluates to 'true' if the assume statement holds in the state.

; yosys-smt2-cover <id> <filename:linenum>
(define-fun |<mod>_c <id>| ((state |<mod>_s|)) Bool (...))
  Each $cover cell is converted into one of this functions. The function
  evaluates to 'true' if the cover statement is activated in the state.
```

Options:

```
-verbose
  this will print the recursive walk used to export the modules.

-stbv
  Use a BitVec sort to represent a state instead of an uninterpreted
  sort. As a side-effect this will prevent use of arrays to model
  memories.

-stdt
  Use SMT-LIB 2.6 style datatypes to represent a state instead of an
  uninterpreted sort.

-nobv
  disable support for BitVec (FixedSizeBitVectors theory). without this
  option multi-bit wires are represented using the BitVec sort and
  support for coarse grain cells (incl. arithmetic) is enabled.

-nomem
  disable support for memories (via ArraysEx theory). this option is
  implied by -nobv. only $mem cells without merged registers in
  read ports are supported. call "memory" with -nordff to make sure
  that no registers are merged into $mem read ports. '<mod>_m' functions
  will be generated for accessing the arrays that are used to represent
  memories.

-wires
  create '<mod>_n' functions for all public wires. by default only ports,
  registers, and wires with the 'keep' attribute are exported.

-tpl <template_file>
  use the given template file. the line containing only the token '%%'
  is replaced with the regular output of this command.
```

(continues on next page)

(continued from previous page)

```
-solver-option <option> <value>
    emit a `; yosys-smt2-solver-option` directive for yosys-smtbmc to write
    the given option as a `(set-option ...)` command in the SMT-LIBv2.
```

[1] For more information on SMT-LIBv2 visit <http://smt-lib.org/> or read David R. Cok's tutorial: <https://smtlib.github.io/jSMTLIB/SMTLIBTutorial.pdf>

Example:

Consider the following module (test.v). We want to prove that the output can never transition from a non-zero value to a zero value.

```
module test(input clk, output reg [3:0] y);
    always @(posedge clk)
        y <= (y << 1) | ^y;
endmodule
```

For this proof we create the following template (test.tpl).

```
; we need QF_UFBV for this proof
(set-logic QF_UFBV)

; insert the auto-generated code here
%%

; declare two state variables s1 and s2
(declare-fun s1 () test_s)
(declare-fun s2 () test_s)

; state s2 is the successor of state s1
(assert (test_t s1 s2))

; we are looking for a model with y non-zero in s1
(assert (distinct (|test_n y| s1) #b0000))

; we are looking for a model with y zero in s2
(assert (= (|test_n y| s2) #b0000))

; is there such a model?
(check-sat)
```

The following yosys script will create a 'test.smt2' file for our proof:

```
read_verilog test.v
hierarchy -check; proc; opt; check -assert
write_smt2 -bv -tpl test.tpl test.smt2
```

Running 'cvc4 test.smt2' will print 'unsat' because y can never transition from non-zero to zero in the test design.

G.245 write_smv - write design to SMV file

```
write_smv [options] [filename]
```

Write an SMV description of the current design.

-verbose

this will print the recursive walk used to export the modules.

-tpl <template_file>

use the given template file. the line containing only the token '%%' is replaced with the regular output of this command.

THIS COMMAND IS UNDER CONSTRUCTION

G.246 write_spice - write design to SPICE netlist file

```
write_spice [options] [filename]
```

Write the current design to an SPICE netlist file.

-big_endian

generate multi-bit ports in MSB first order
(default is LSB first)

-neg net_name

set the net name for constant 0 (default: Vss)

-pos net_name

set the net name for constant 1 (default: Vdd)

-buf DC|subckt_name

set the name for jumper element (default: DC)
(used to connect different nets)

-nc_prefix

prefix for not-connected nets (default: _NC)

-inames

include names of internal (\$-prefixed) nets in outputs
(default is to use net numbers instead)

-top top_module

set the specified module as design top module

G.247 write_table - write design as connectivity table

```
write_table [options] [filename]
```

Write the current design as connectivity table. The output is a tab-separated ASCII table with the following columns:

```
module name
cell name
cell type
cell port
direction
signal
```

module inputs and outputs are output using cell type and port '-' and with 'pi' (primary input) or 'po' (primary output) or 'pio' as direction.

G.248 write_verilog - write design to Verilog file

```
write_verilog [options] [filename]
```

Write the current design to a Verilog file.

```
-sv
    with this option, SystemVerilog constructs like always_comb are used

-norename
    without this option all internal object names (the ones with a dollar
    instead of a backslash prefix) are changed to short names in the
    format '_<number>_'.

-renameprefix <prefix>
    insert this prefix in front of auto-generated instance names

-noattr
    with this option no attributes are included in the output

-attr2comment
    with this option attributes are included as comments in the output

-noexpr
    without this option all internal cells are converted to Verilog
    expressions.

-noparallelcase
    With this option no parallel_case attributes are used. Instead, a case
    statement that assigns don't-care values for priority dependent inputs
    is generated.

-siminit
```

(continues on next page)

(continued from previous page)

add initial statements with hierarchical refs to initialize FFs when in -noexpr mode.

-nodec

32-bit constant values are by default dumped as decimal numbers, not bit pattern. This option deactivates this feature and instead will write out all constants in binary.

-decimal

dump 32-bit constants in decimal and without size and radix

-nohex

constant values that are compatible with hex output are usually dumped as hex values. This option deactivates this feature and instead will write out all constants in binary.

-nostr

Parameters and attributes that are specified as strings in the original input will be output as strings by this back-end. This deactivates this feature and instead will write string constants as binary numbers.

-simple-lhs

Connection assignments with simple left hand side without concatenations.

-extmem

instead of initializing memories using assignments to individual elements, use the '\$readmemh' function to read initialization data from a file. This data is written to a file named by appending a sequential index to the Verilog filename and replacing the extension with '.mem', e.g. 'write_verilog -extmem foo.v' writes 'foo-1.mem', 'foo-2.mem' and so on.

-defparam

use 'defparam' statements instead of the Verilog-2001 syntax for cell parameters.

-blackboxes

usually modules with the 'blackbox' attribute are ignored. with this option set only the modules with the 'blackbox' attribute are written to the output file.

-selected

only write selected modules. modules must be selected entirely or not at all.

-v

verbose output (print new names of all renamed wires and cells)

Note that RTLIL processes can't always be mapped directly to Verilog always blocks. This frontend should only be used to export an RTLIL

(continues on next page)

(continued from previous page)

netlist, i.e. after the "proc" pass has been used to convert all processes to logic networks and registers. A warning is generated when this command is called on a design with RTLIL processes.

G.249 write_xaiger - write design to XAIGER file

```
write_xaiger [options] [filename]
```

Write the top module (according to the (* top *) attribute or if only one module is currently selected) to an XAIGER file. Any non \$_NOT_, \$_AND_, (optionally \$_DFF_N_, \$_DFF_P_), or non (* abc9_box *) cells will be converted into psuedo-inputs and pseudo-outputs. Whitebox contents will be taken from the equivalent module in the '\$abc9_holes' design, if it exists.

```
-ascii
    write ASCII version of AIGER format

-map <filename>
    write an extra file with port and box symbols

-dff
    write $_DFF_[NP]_ cells
```

G.250 xilinx_dffopt - Xilinx: optimize FF control signal usage

```
xilinx_dffopt [options] [selection]
```

Converts hardware clock enable and set/reset signals on FFs to emulation using LUTs, if doing so would improve area. Operates on post-techmap Xilinx cells (LUT*, FD*).

```
-lut4
    Assume a LUT4-based device (instead of a LUT6-based device).
```

G.251 xilinx_dsp - Xilinx: pack resources into DSPs

```
xilinx_dsp [options] [selection]
```

Pack input registers (A2, A1, B2, B1, C, D, AD; with optional enable/reset), pipeline registers (M; with optional enable/reset), output registers (P; with optional enable/reset), pre-adder and/or post-adder into Xilinx DSP resources.

Multiply-accumulate operations using the post-adder with feedback on the 'C' input will be folded into the DSP. In this scenario only, the 'C' input can be used to override the current accumulation result with a new value, which will

(continues on next page)

(continued from previous page)

be added to the multiplier result to form the next accumulation result.

Use of the dedicated 'PCOUT' -> 'PCIN' cascade path is detected for 'P' -> 'C' connections (optionally, where 'P' is right-shifted by 17-bits and used as an input to the post-adder -- a pattern common for summing partial products to implement wide multipliers). Limited support also exists for similar cascading for A and B using '[AB]COUT' -> '[AB]CIN'. Currently, cascade chains are limited to a maximum length of 20 cells, corresponding to the smallest Xilinx 7 Series device.

This pass is a no-op if the scratchpad variable 'xilinx_dsp.mulonly' is set to 1.

Experimental feature: addition/subtractions less than 12 or 24 bits with the '(* use_dsp="simd" *)' attribute attached to the output wire or attached to the add/subtract operator will cause those operations to be implemented using the 'SIMD' feature of DSPs.

Experimental feature: the presence of a '\$ge' cell attached to the registered P output implementing the operation "(P >= <power-of-2>)" will be transformed into using the DSP48E1's pattern detector feature for overflow detection.

```
-family {xcup|xcu|xc7|xc6v|xc5v|xc4v|xc6s|xc3sda}
    select the family to target
    default: xc7
```

G.252 xilinx_srl - Xilinx shift register extraction

```
xilinx_srl [options] [selection]
```

This pass converts chains of built-in flops (bit-level: \$_DFF_[NP]_, \$_DFFE_* and word-level: \$dff, \$dffe) as well as Xilinx flops (FDRE, FDRE_1) into a \$_XILINX_SHREG cell. Chains must be of the same cell type, clock, clock polarity, enable, and enable polarity (where relevant). Flops with resets cannot be mapped to Xilinx devices and will not be inferred.

```
-minlen N
    min length of shift register (default = 3)

-fixed
    infer fixed-length shift registers.

-variable
    infer variable-length shift registers (i.e. fixed-length shifts where
    each element also fans-out to a $shiftx cell).
```

G.253 xprop - formal x propagation

```
xprop [options] [selection]
```

This pass transforms the circuit into an equivalent circuit that explicitly encodes the propagation of x values using purely 2-valued logic. On the interface between xprop-transformed and non-transformed parts of the design, appropriate conversions are inserted automatically.

-split-inputs

-split-outputs

-split-ports

Replace each input/output/port with two new ports, one carrying the defined values (named <portname>_d) and one carrying the mask of which bits are x (named <portname>_x). When a bit in the <portname>_x is set the corresponding bit in <portname>_d is ignored for inputs and guaranteed to be 0 for outputs.

-split-public

Replace each public non-port wire with two new wires, one carrying the defined values (named <wirename>_d) and one carrying the mask of which bits are x (named <wirename>_x). When a bit in the <portname>_x is set the corresponding bit in <wirename>_d is guaranteed to be 0 for outputs.

-assume-encoding

Add encoding invariants as assumptions. This can speed up formal verification tasks.

-assert-encoding

Add encoding invariants as assertions. Used for testing the xprop pass itself.

-assume-def-inputs

Assume all inputs are fully defined. This adds corresponding assumptions to the design and uses these assumptions to optimize the xprop encoding.

-required

Produce a runtime error if any encountered cell could not be encoded.

-formal

Produce a runtime error if any encoded cell uses a signal that is neither known to be non-x nor driven by another encoded cell.

-debug-asserts

Add assertions checking that the encoding used by this pass never produces x values within the encoded signals.

G.254 zinit - add inverters so all FF are zero-initialized

```
zinit [options] [selection]
```

Add inverters as needed to make all FFs zero-initialized.

```
-all
```

```
    also add zero initialization to uninitialized FFs
```
